Week 10

# Permissionless consensus, multi-valued history consensus

Bitcoin, distributed ledger tech (DLT):

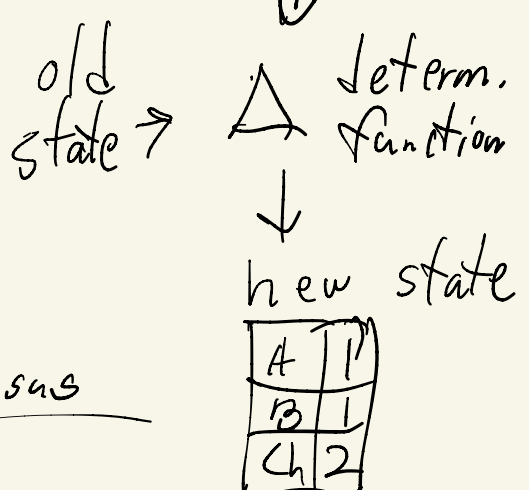

- Information-based money: a ledger  
 ledger: history of transactions

1. Conservative

$\rightarrow$ A's .5	C .7	pub keys
$\rightarrow$ B' .5	D .2	

= 1 sig<sub>A,B</sub>  $\leq$  inputs

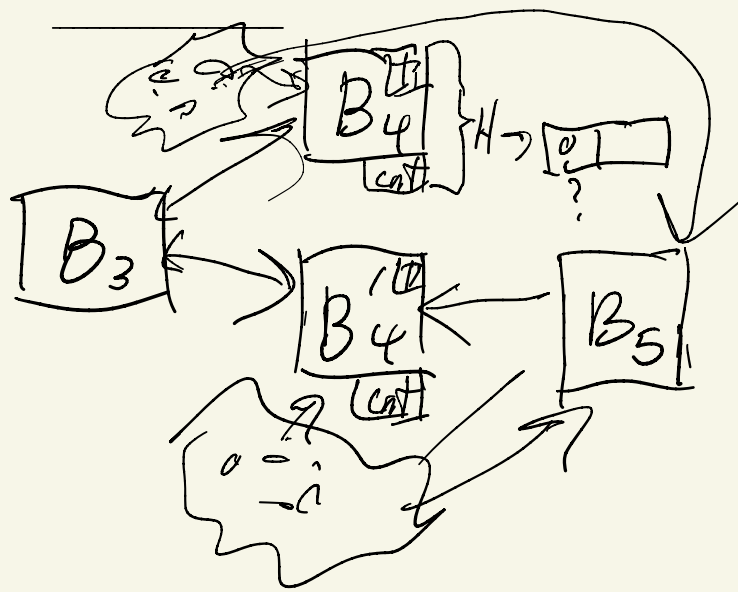

diff: TX fee  $\rightarrow$  miner

2. "Coinbase" - creates money

- Key ideas:
- ledger publicly indicates "who owns what"
  - miners rewarded for adding blocks
  - hinges on history consensus
  - no double-spending

# Bitcoin consensus

- who gets to add a block, on what basis?
- almost all of real cost is from PoW
- deliberate, artificial cost to creating/adding blks
- a (honest) miner only accepts valid blocks w/ PoW
- deterministic agreed-upon validity function
- but which next valid block? (consensus)

preference for "more PoW effort"

→ temporary inconsistencies

→ history rewriting  
(in last few blocks)

→ statistically, longest/heaviest  
always "wins" eventually

"51% attacks"

# Permissioned consensus, on histories / ledgers

- "Multi-Paxos" - history
- Raft: re-formulation of Paxos
- PBFT: Castro / Liskov

## Key challenges:

- Pacing: when does a TX/blk get added?

- Paxos/Raft/PBFT/...: leader-based

what if leader fails?  $\rightarrow$  synchrony assumptions

$\rightarrow$  complexity of leader changes

$\rightarrow$  DoS opportunities

- Bitcoin: PoW: tuned for target of  $\approx 10$  mins

- Asynchronous pacing / consensus:

can always progress as fast as network communication permits?

# Asynchronous pacing, consensus

## - Threshold Logical Clock (TLC)

- a single (integer) notion of "time-steps" across group
- paced: no node "get ahead" of (majority) of the rest (vs Lamport clocks)

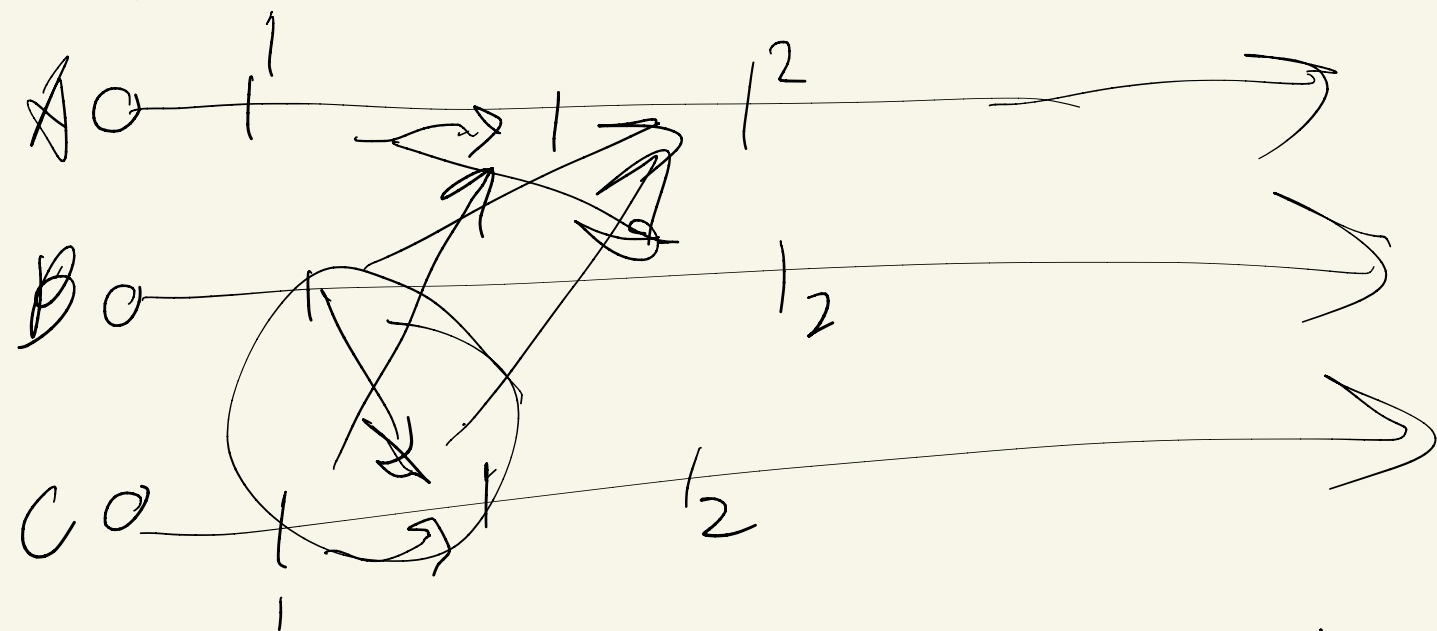

## - HW3: using Paxos (example)

paxos - needs  
synchrony to  
achieve liveness

papers)  
- prepare / reserve  
- propose / commit

# Asynchronous TLCs, "Que Sera Consensus" (QSC)

each node at step  $s$  waits to proceed to  $s+1$ :

- received updates from threshold  $t$  of other nodes
- at least  $t$  nodes have all received updates from at least  $t$  nodes

= I know a set  $|M| \geq t$  that have been received by at least  $t$  nodes
