

Lecture 8:

The Network Layer

Katerina Argyraki, EPFL

Outline

- Network-layer **functions**
 - ▶ forwarding
 - ▶ routing
- Network-layer **types**
 - ▶ virtual-circuit networks
 - ▶ datagram networks
- **IP forwarding**
- **IP routing**

Forwarding

- **Local** process that takes place at a router and determines output link for each packet
- How: **read** value from packet's network-layer header, **search** forwarding table for output link

Routing

- **Network-wide** process that populates forwarding tables
- How: routing algorithm run on a logically centralised **network controller** or the **routers themselves**

Outline

- Network-layer **functions**
 - ▶ forwarding
 - ▶ routing
- Network-layer **types**
 - ▶ virtual-circuit networks
 - ▶ datagram networks
- **IP forwarding**
- **IP routing**

IP forwarding

- Router's forwarding table maps **IP prefixes to output links**
- Reads **destination IP address** from packet's network-layer header
- Performs **longest prefix matching**
 - ▶ finds, in its forwarding table, the IP prefix that matches the dst IP address the best

Outline

- Network-layer functions
 - forwarding
 - routing
- Network-layer types
 - virtual-circuit networks
 - datagram networks
- IP forwarding
- **IP routing**

dest. prefix	output link
52.85.0.0/16	1
8.0.0.0/8	2
12.17.5.0/24	2
...	...

dest. prefix	output link
52.85.0.0/16	3
8.0.0.0/8	1
12.17.5.0/24	2

dest.	out. link
8.0.0.0/8	1
5.0.0.0/8	2

first-hop router for IP subnet 8.0.0.0/8

link costs

could represent:
 propagation delay
 usage fee
 ...

least-cost path from u to z: u v z

least-cost path from u to v: u v

Least-cost path routing

- Goal: find **least-cost path** from each source router to each destination router

dest.	next hop	cost
z		
v		

dest.	next hop	cost

v	v	1
x	x	2

dest.	next hop	cost
z	v y x	1 4 3
v	v	1
x	x	2

Link-state routing algorithm for source u

- Input: router graph & link costs
- Output: least-cost path from source router u to every other router

Link-state routing algorithm for source u

- Centralized algorithm: runs on a single entity
- Option #1: Router u runs the algorithm
- Option #2: Separate computer (“network controller”) runs the algorithm

Dijkstra's algorithm

- At each step, consider a new router
 - starting from "closest" neighbor
- Check whether current paths can be improved
 - by using that router as an intermediate point
- End when no improvement is possible

Distance-vector routing algorithm

- Input to each router: local link costs & neighbor messages
- Output of each router: least-cost path to every other router

Distance-vector routing algorithm

- Distributed algorithm
- All routers run it “together”: neighbors exchange and react to each other’s messages

Bellman-Ford algorithm

- All neighbors exchange information
- Each router checks whether it can improve current paths by leveraging the new information
- Ends when no improvement is possible

count-to-infinity
scenario

	x	y	z
y	8	0	1
z	7	1	0

Problem with Bellman-Ford

- Routing loop
 - ▶ z routes through y, y routes through x
 - ▶ y loses connectivity to x
 - ▶ y decides to route through z
- Can take very long to resolve
 - ▶ count-to-infinity scenario

poisoned reverse

	x	y	z
y	2	0	1
z	∞	1	0

	x	y	z
y	2	0	1
z	3	1	0

poisoned reverse

	x	y	z
y	∞	0	1
z	∞	1	0

	x	y	z
y	2	0	1
z	3	1	0

poisoned reverse

	x	y	z
y	∞	0	1
z	∞	1	0

	x	y	z
y	∞	0	1
z	3	1	0

poisoned reverse

	x	y	z
y	∞	0	1
z	∞	1	0

	x	y	z
y	∞	0	1
z	7	1	0

poisoned reverse

	x	y	z
y	∞	0	1
z	7	1	0

	x	y	z
y	∞	0	1
z	7	1	0

	x	y	z
y	8	0	1
z	7	1	0

poisoned reverse

	x	y	z
y	∞	0	1
z	7	1	0

Solution

- **Poisoned reverse**
 - ▶ if z routes to x through y,
z advertises to y that its cost to x infinite
 - ▶ y never decides to route to x through z
- **Algorithm re-converges quickly**
 - ▶ avoids count-to-infinity scenario

Link-state + distance-vector

- They solve the **same problem**:
compute the least-cost path
from each source router
to each destination router

Link-state vs. distance-vector

- Link state: each entity first obtains **complete view** of the network, then computes the least-cost paths
- Distance vector: each entity obtains **incrementally** new information about the network at every round

dest.	out. link
5.0.0.0/8	3
8.0.0.0/8	1

dest.	out. link
8.0.0.0/8	1
5.0.0.0/8	3

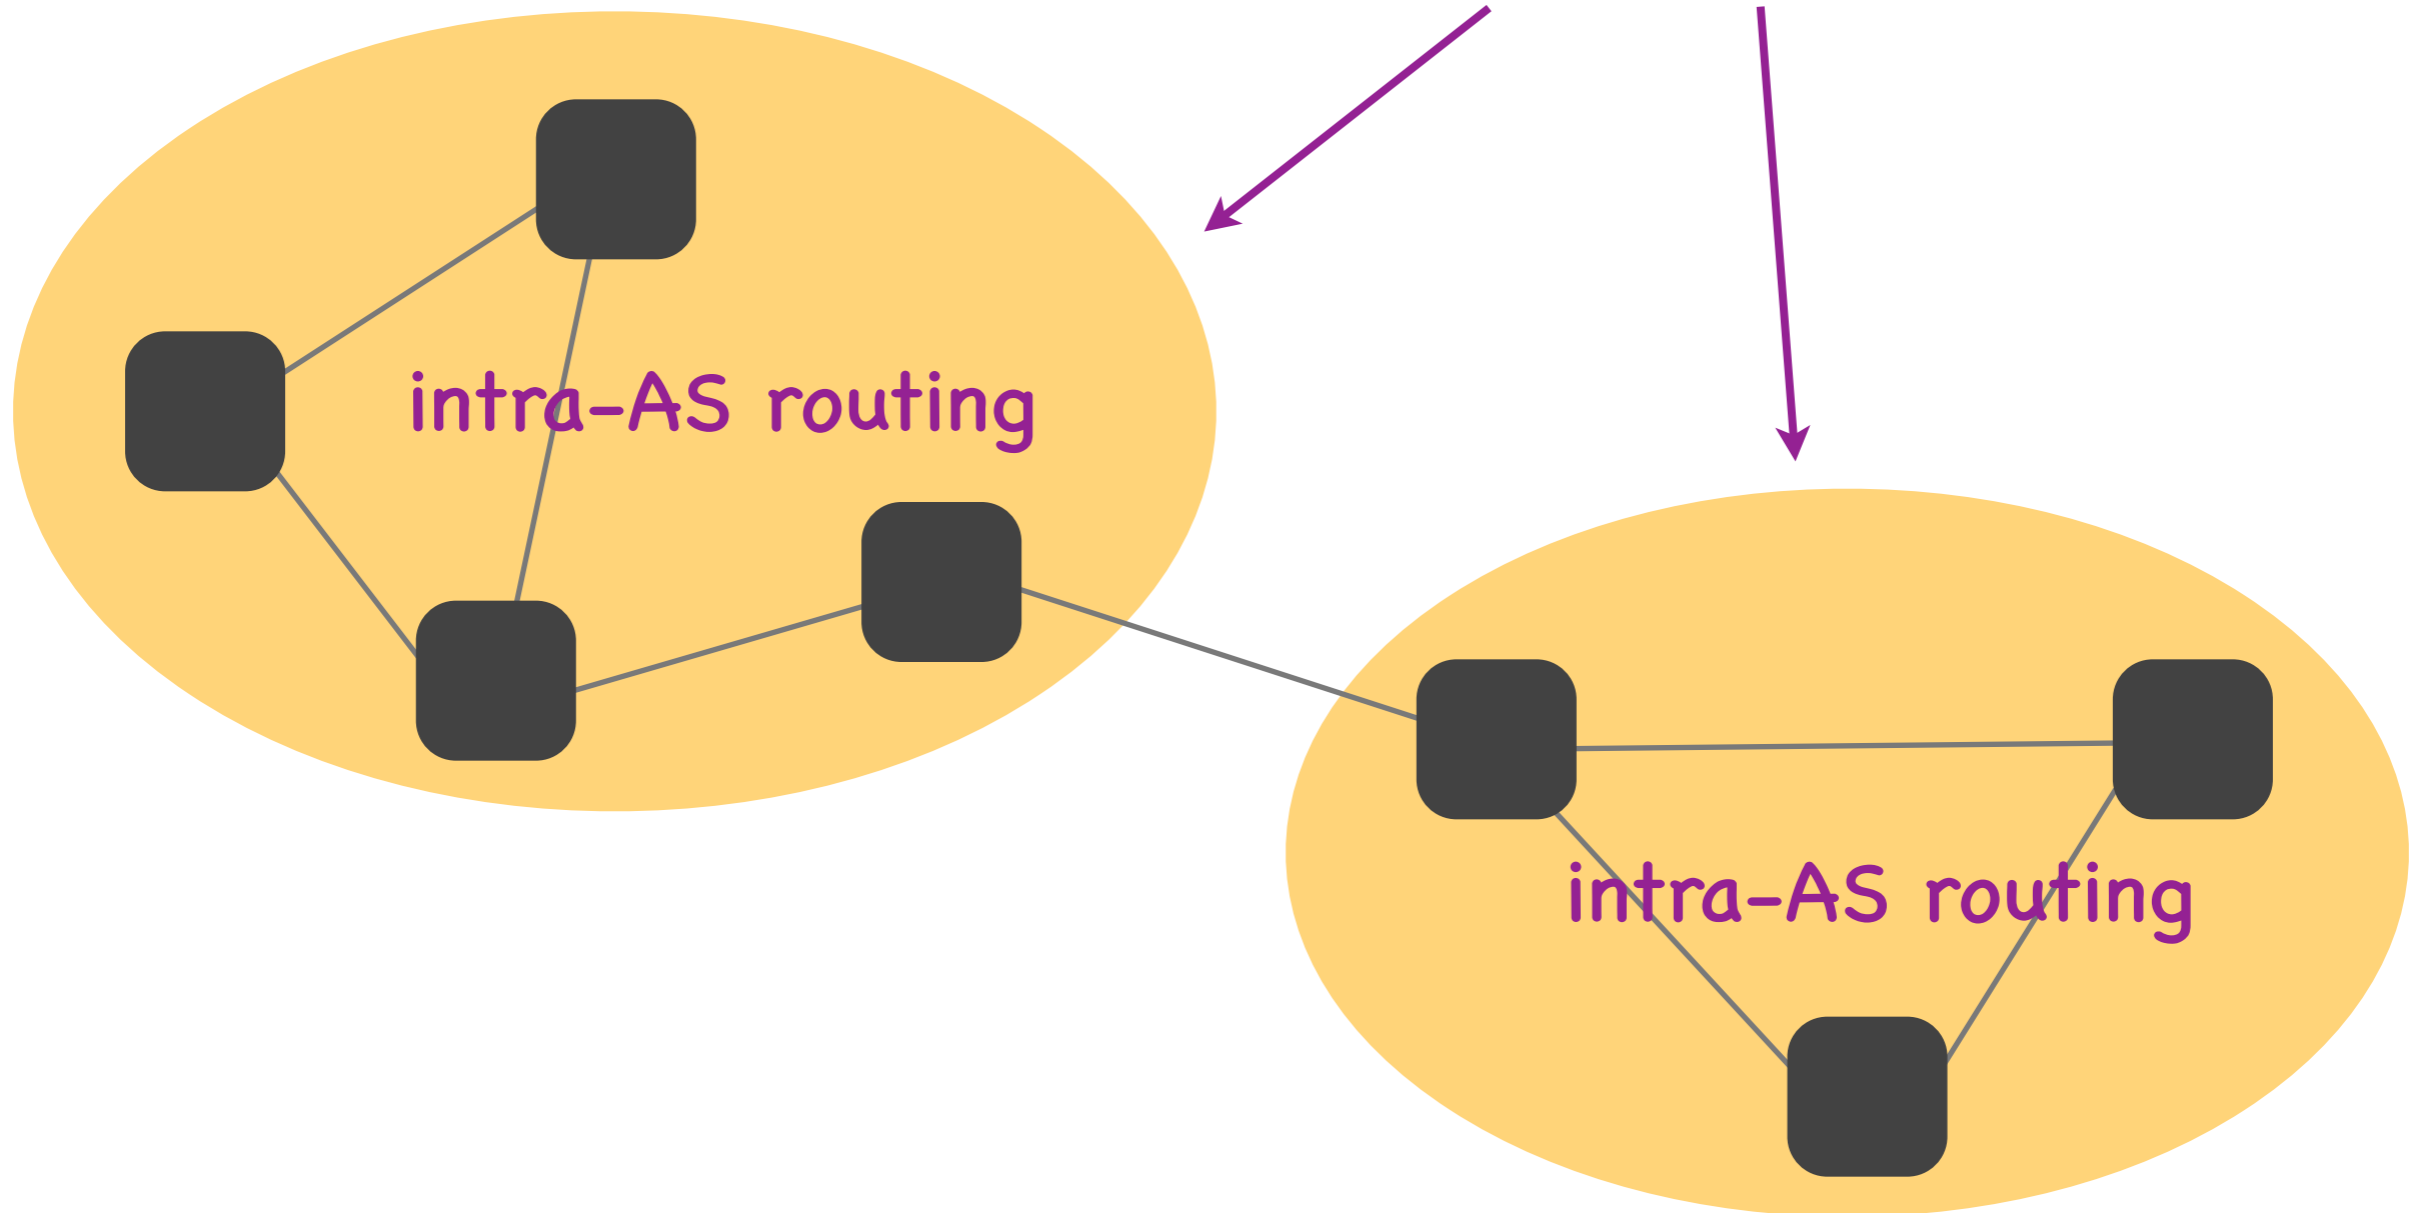

dest.	next hop	IP prefixes
z	v	8.0.0.0/8

dest.	next hop	IP prefixes
u	v	5.0.0.0/8

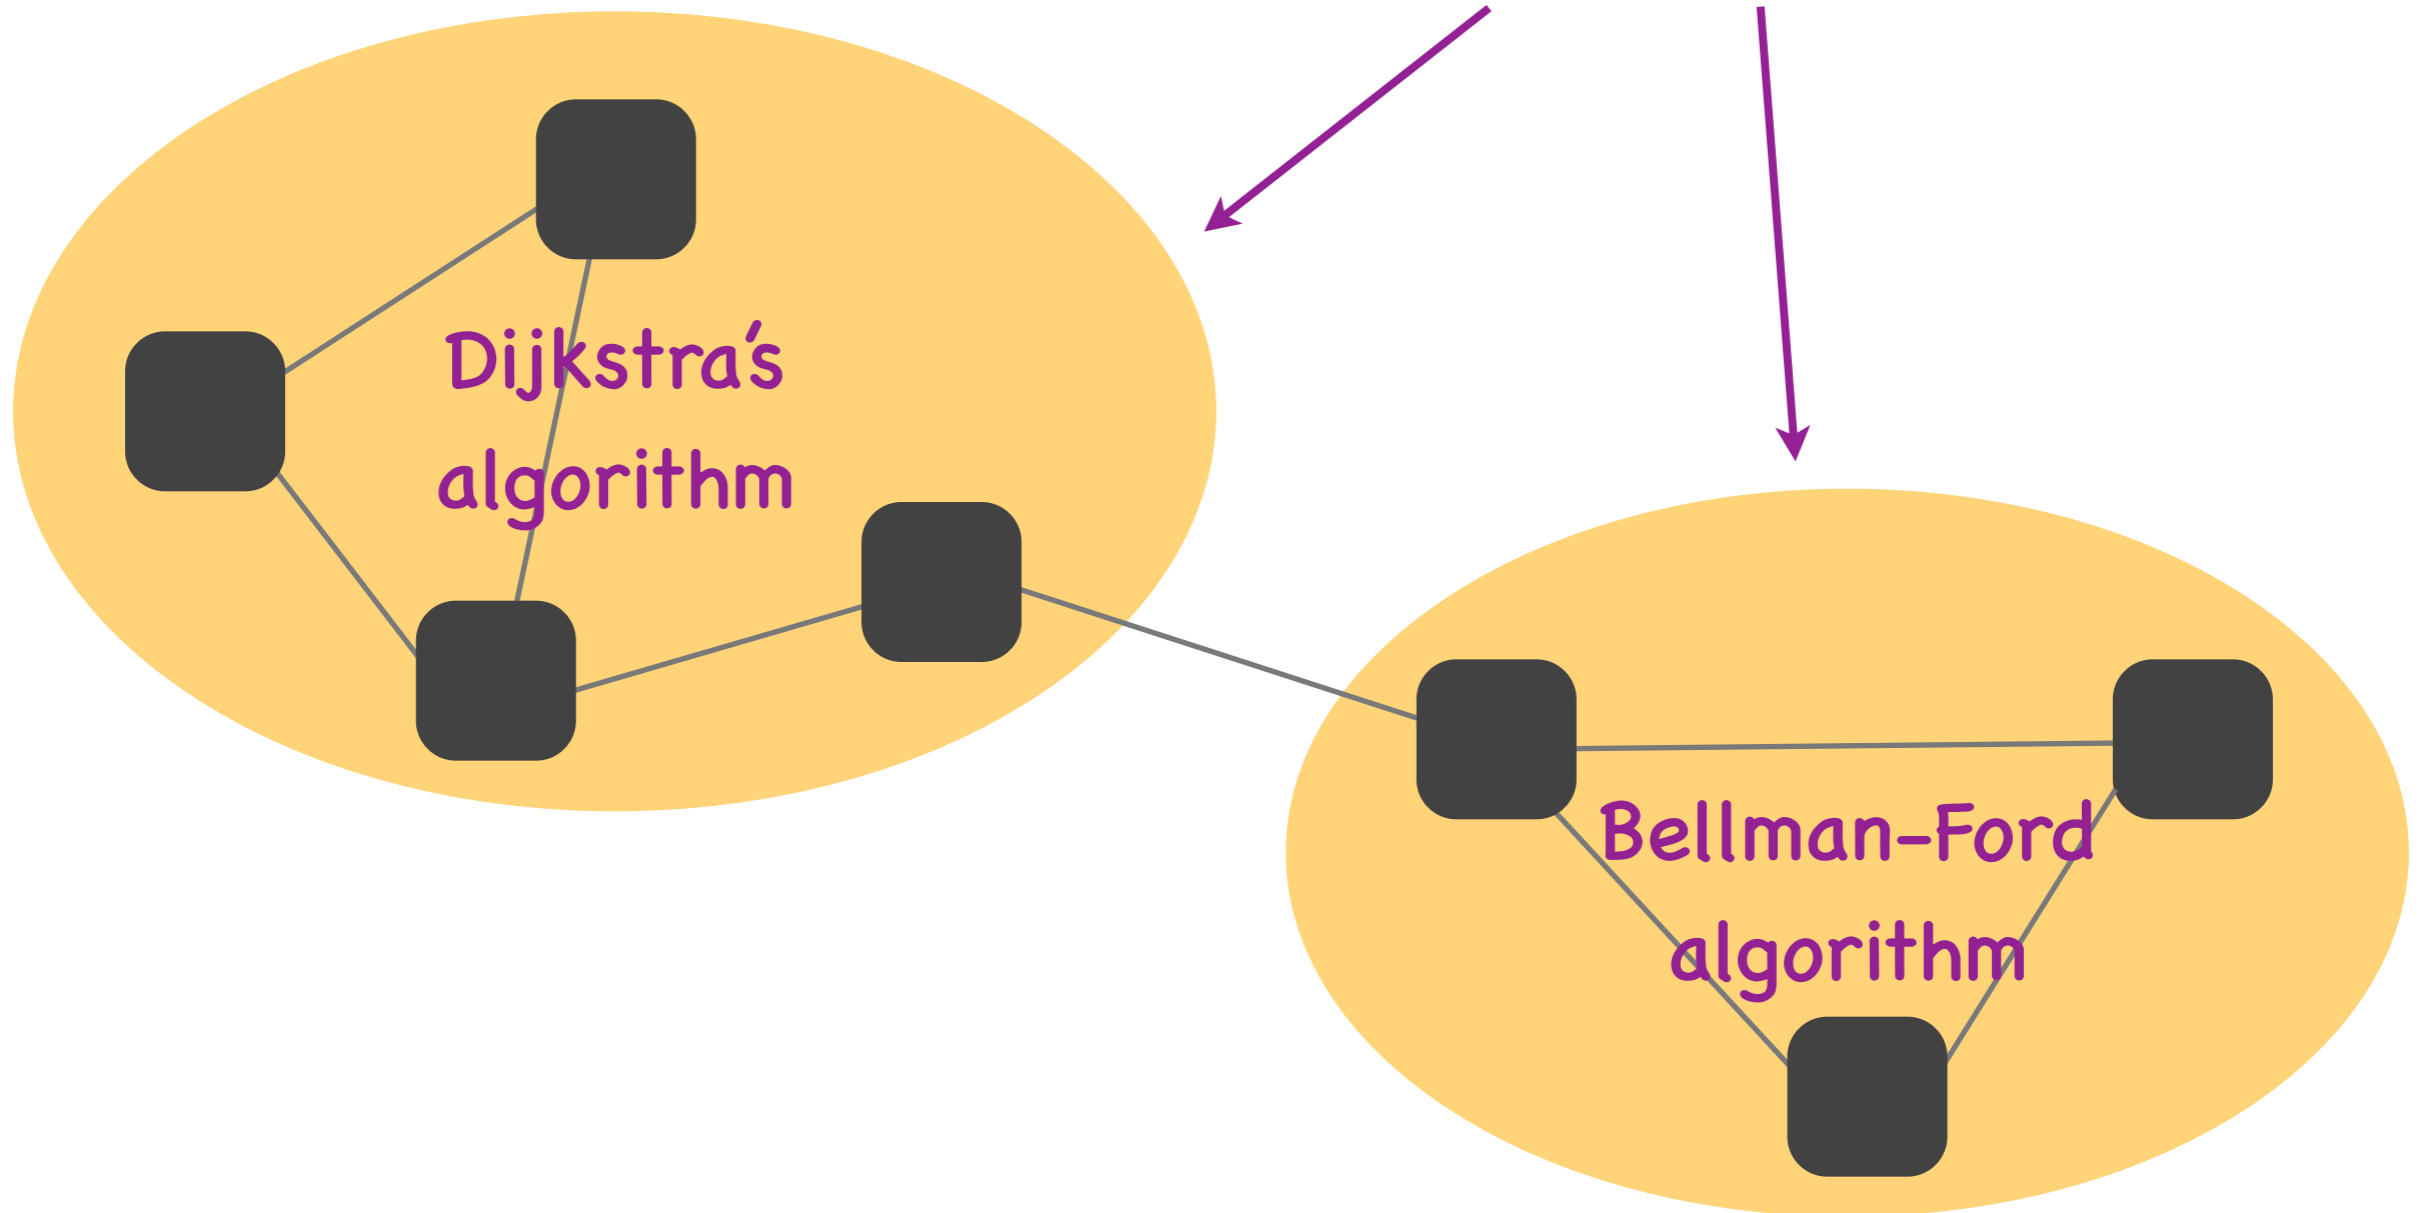

Internet routing challenges

- **Scale**
 - ▶ link-state would cause flooding
 - ▶ distance-vector would not converge
- **Administrative autonomy**
 - ▶ an ISP may not want to do least-cost routing
 - ▶ may want to hide its link costs from the world

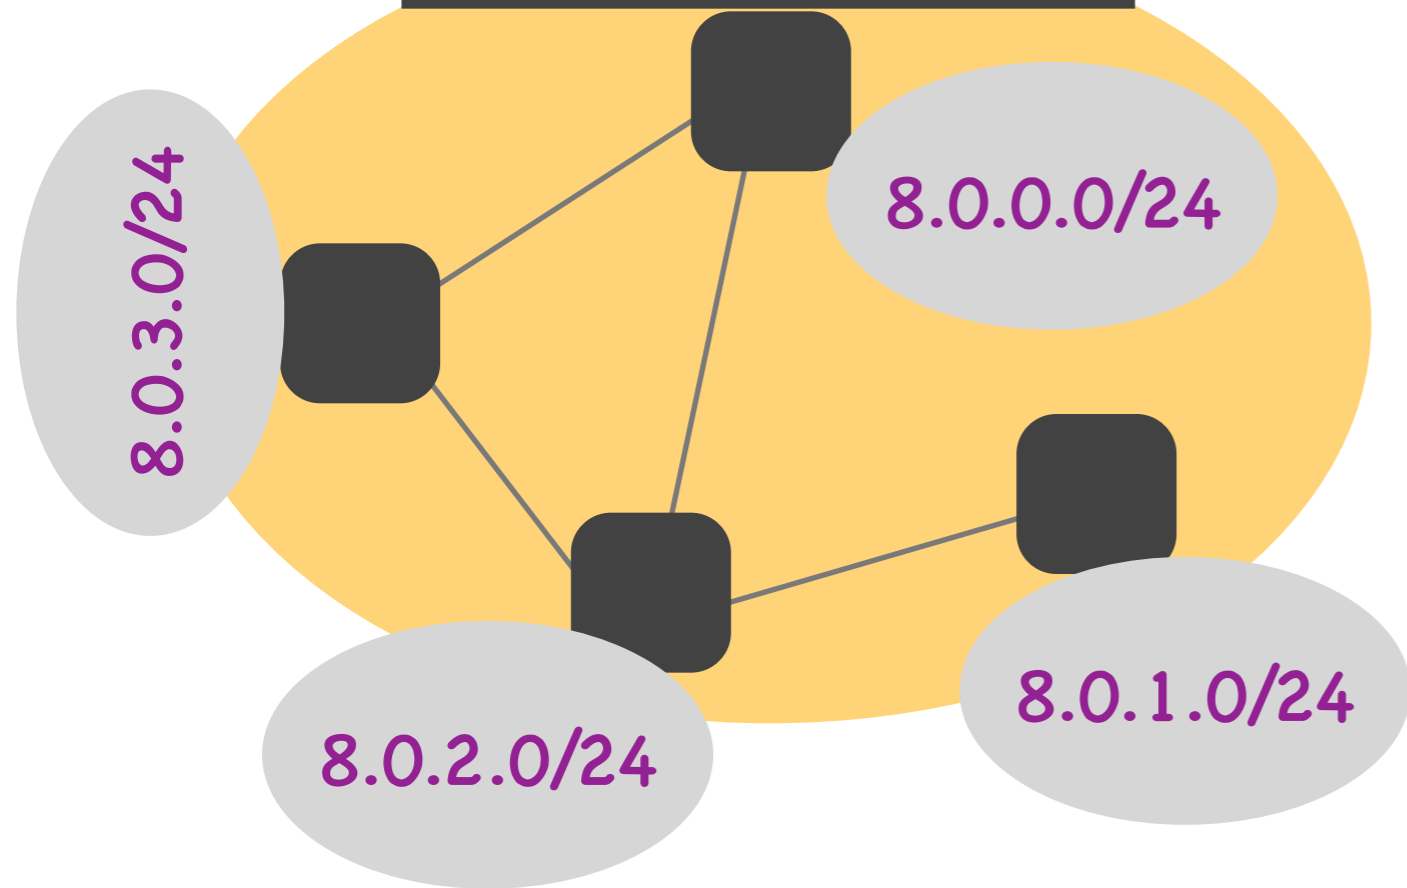

Autonomous Systems

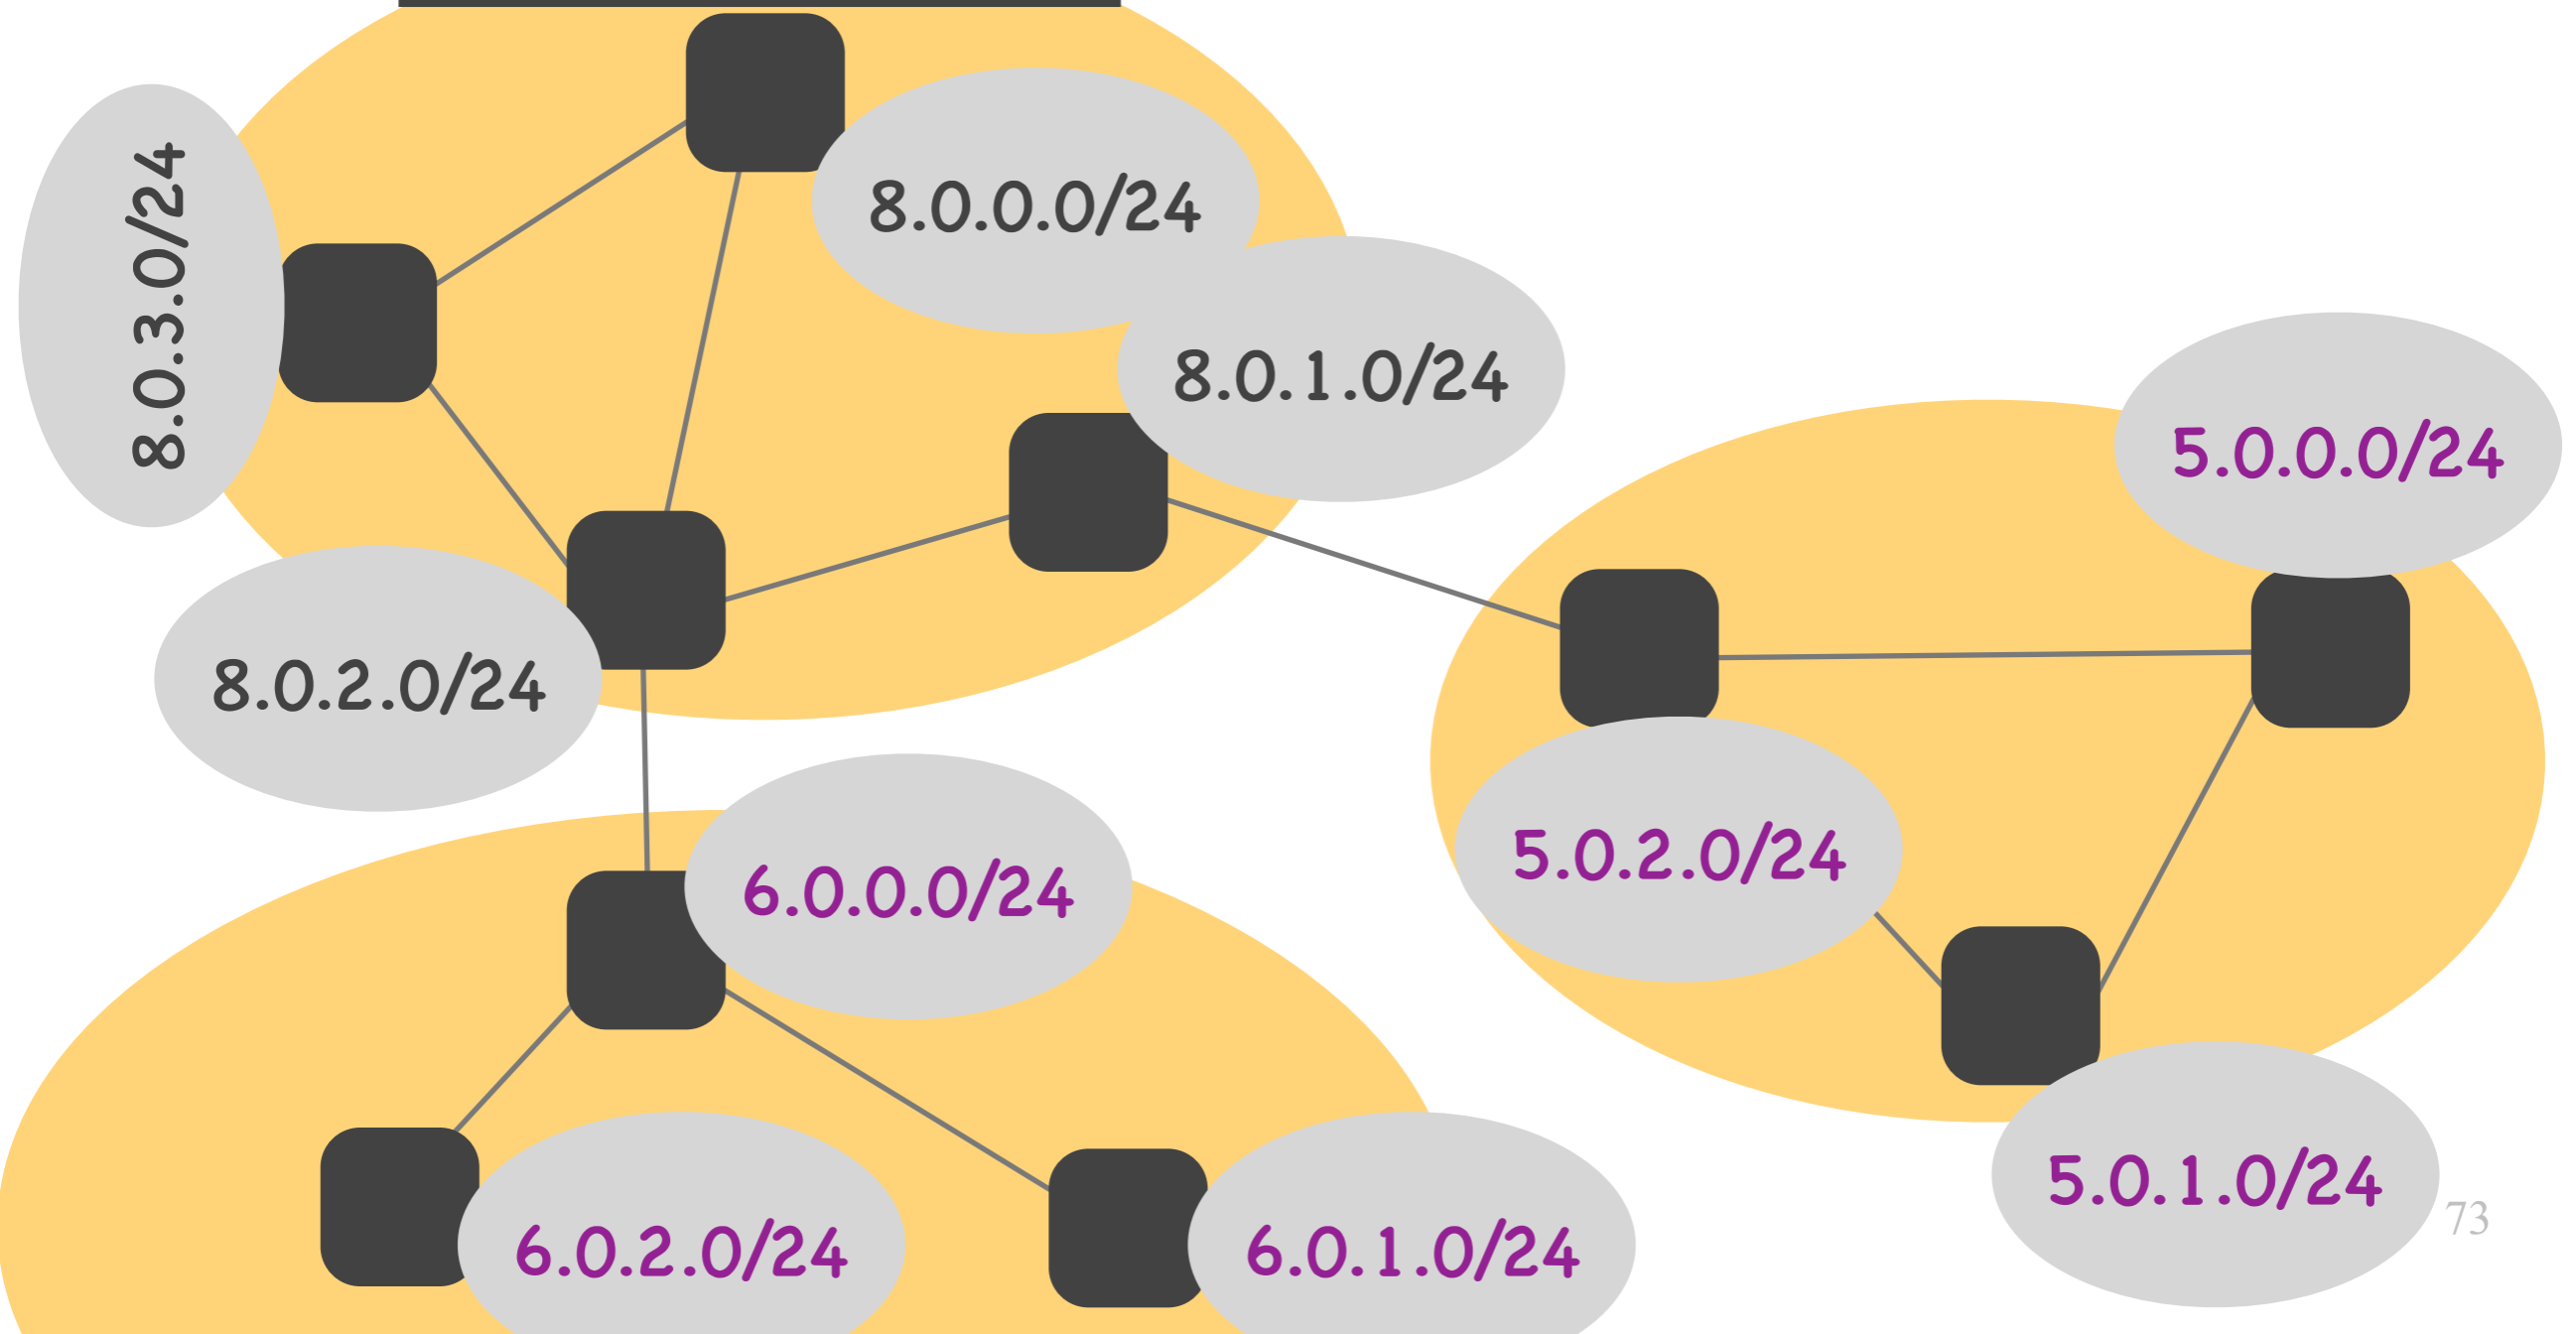

Autonomous Systems

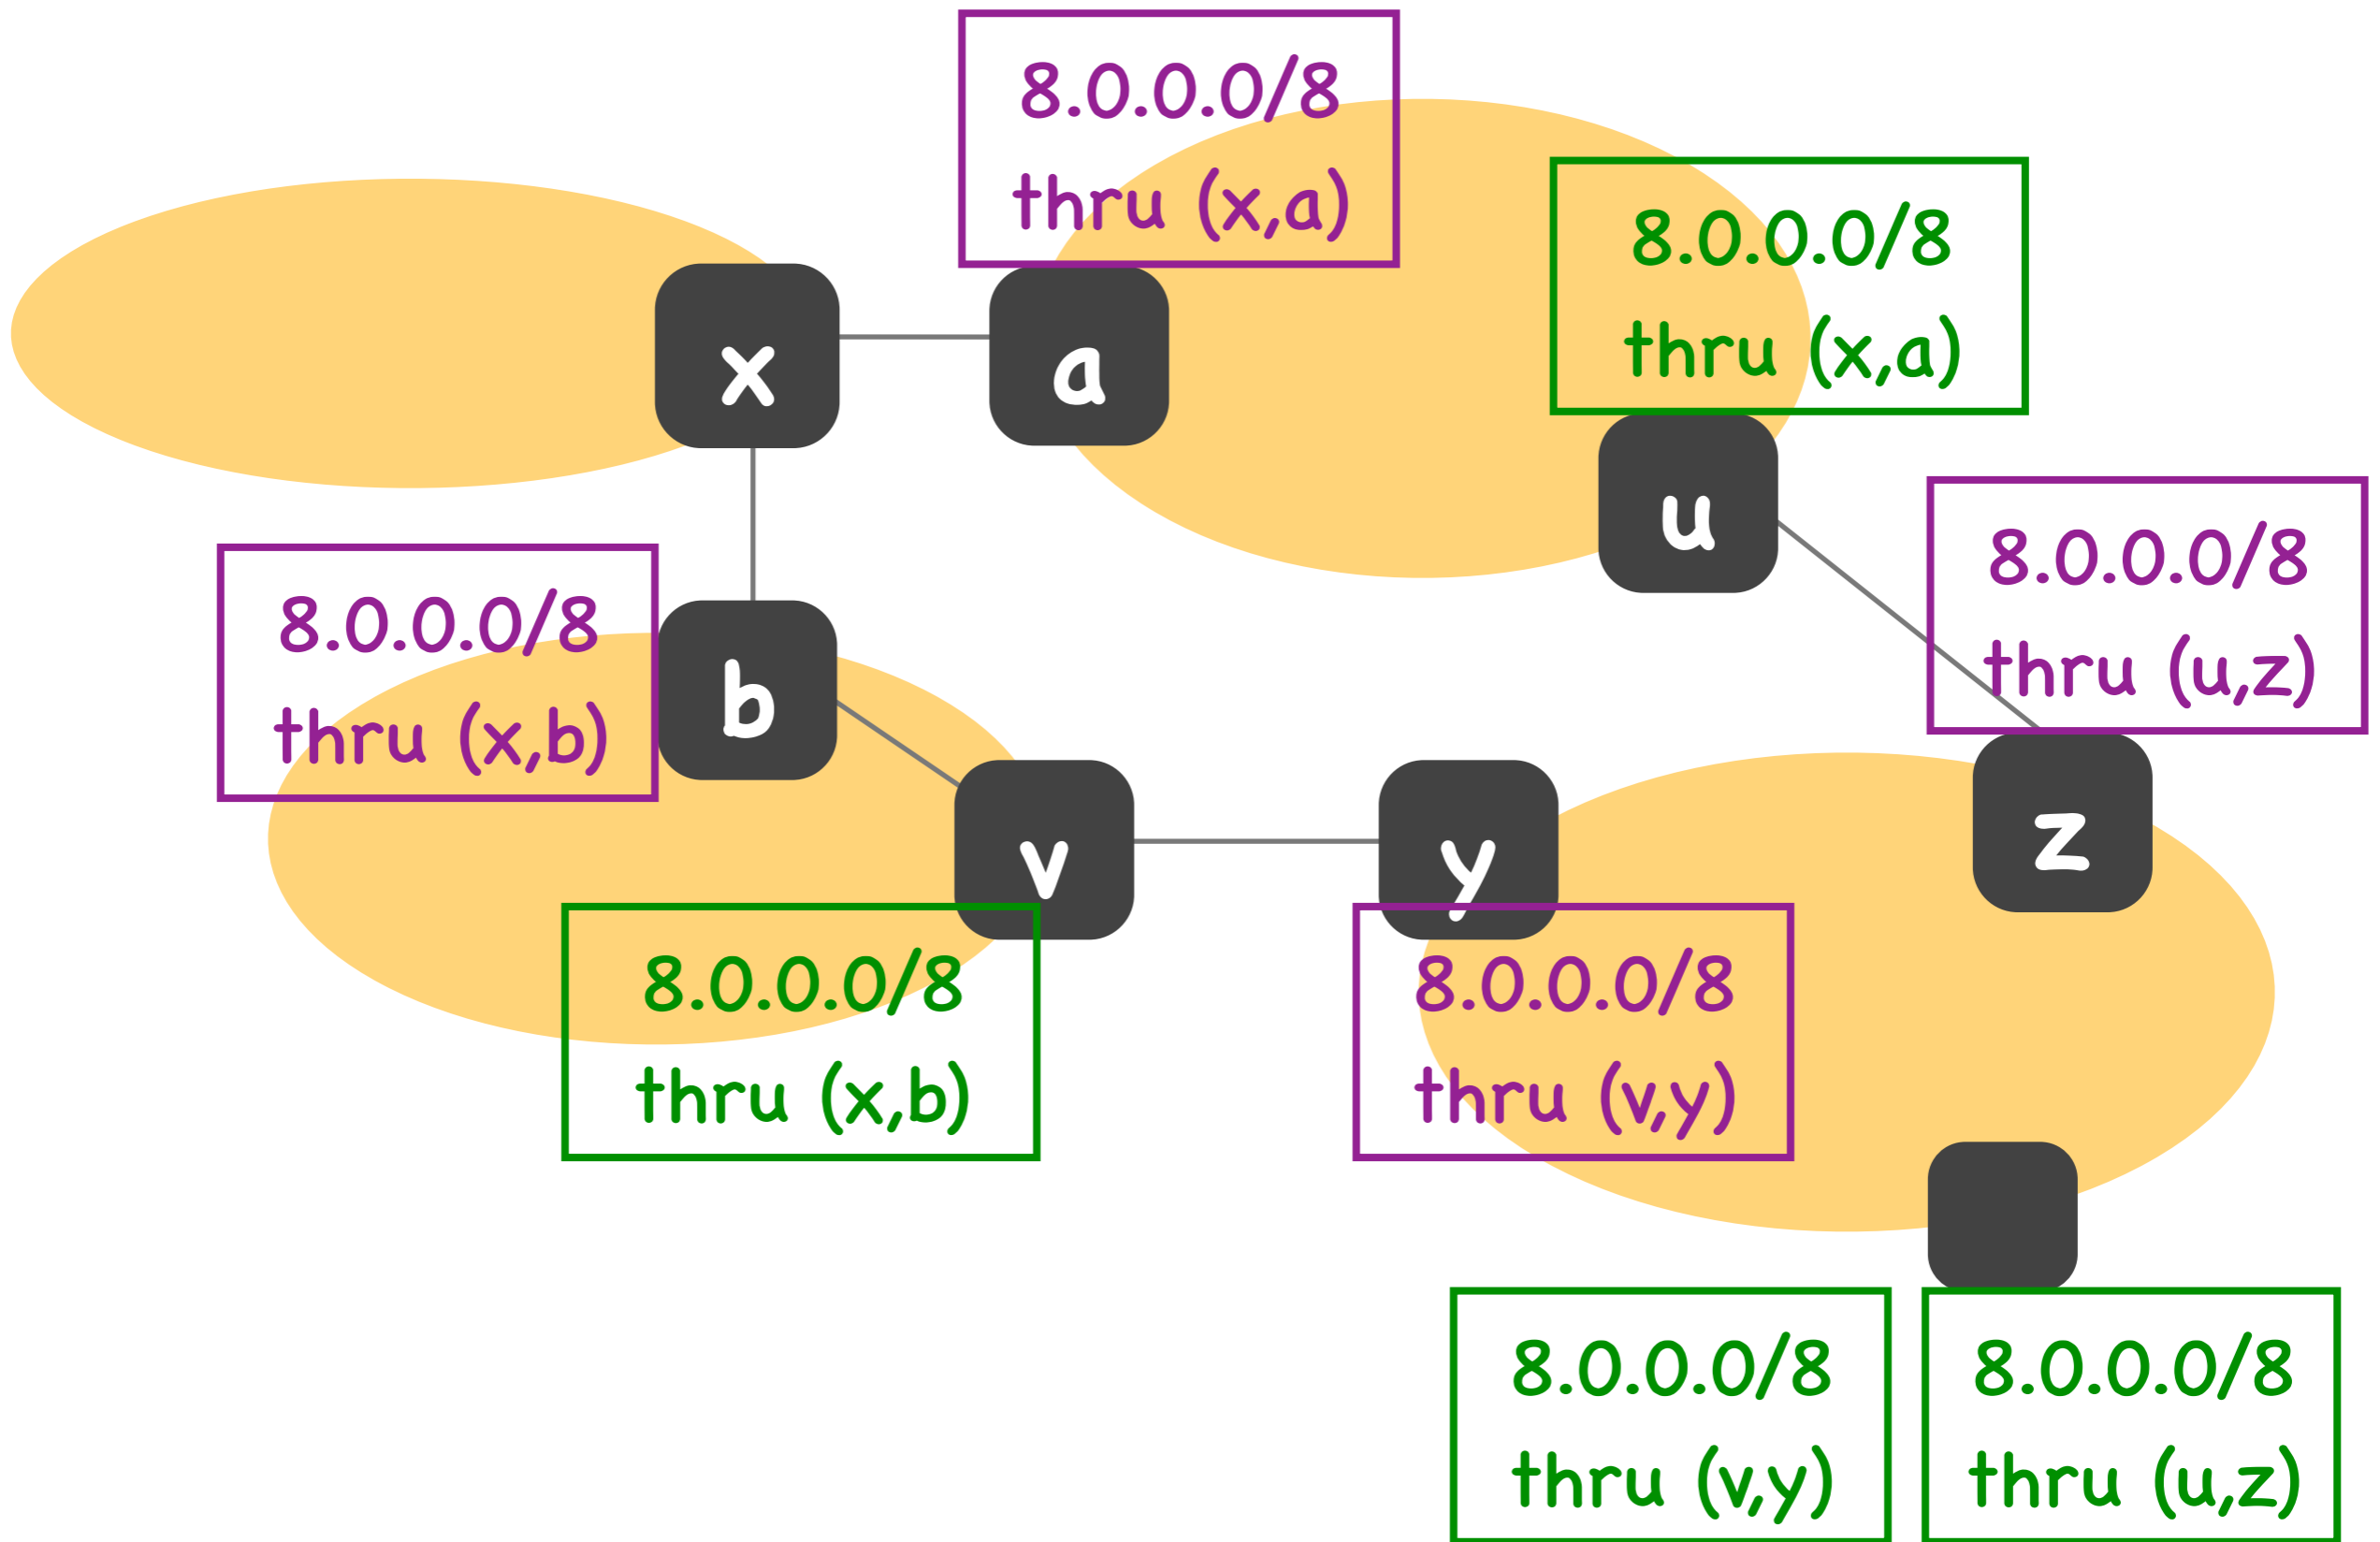

dest.	out. link
8.0.0.0/24	1
8.0.1.0/24	2
8.0.3.0/24	3
8.0.4.0/24	2

dest.	out. link
8.0.0.0/24	2
8.0.1.0/24	3
8.0.2.0/24	2
8.0.3.0/24	2
5.0.0.0/8	2
6.0.0.0/8	2

Internet routing

- Each router learns one route to each IP subnet in local AS
- Each router learns one or a few routes to each foreign AS
 - but not one route to each IP subnet of each foreign AS

Inter-AS routing

- Run by **all border routers** between ASes
- Goal: **propagate routes outside** local AS
 - ▶ each border router talks to external neighbors (eBGP)
 - ▶ and to the other border routers of the local AS (iBGP)
- **BGP** = Border Gateway Protocol

Intra-AS routing

- Run by **all routers in the same AS**
- Goal: **propagate routes within local AS**
 - ▶ each router advertizes routes to its local IP subnets
 - ▶ and potentially routes to other ASes that it has learned through BGP
- OSPF, RIP, ...

Internet routing challenges

- **Scale**
 - ▶ link-state would cause flooding
 - ▶ distance-vector would not converge
- **Administrative autonomy**
 - ▶ an ISP may not want to do least-cost routing
 - ▶ may want to hide its link costs from the world
