

Lecture 10:

# The Link Layer

Katerina Argyraki, EPFL

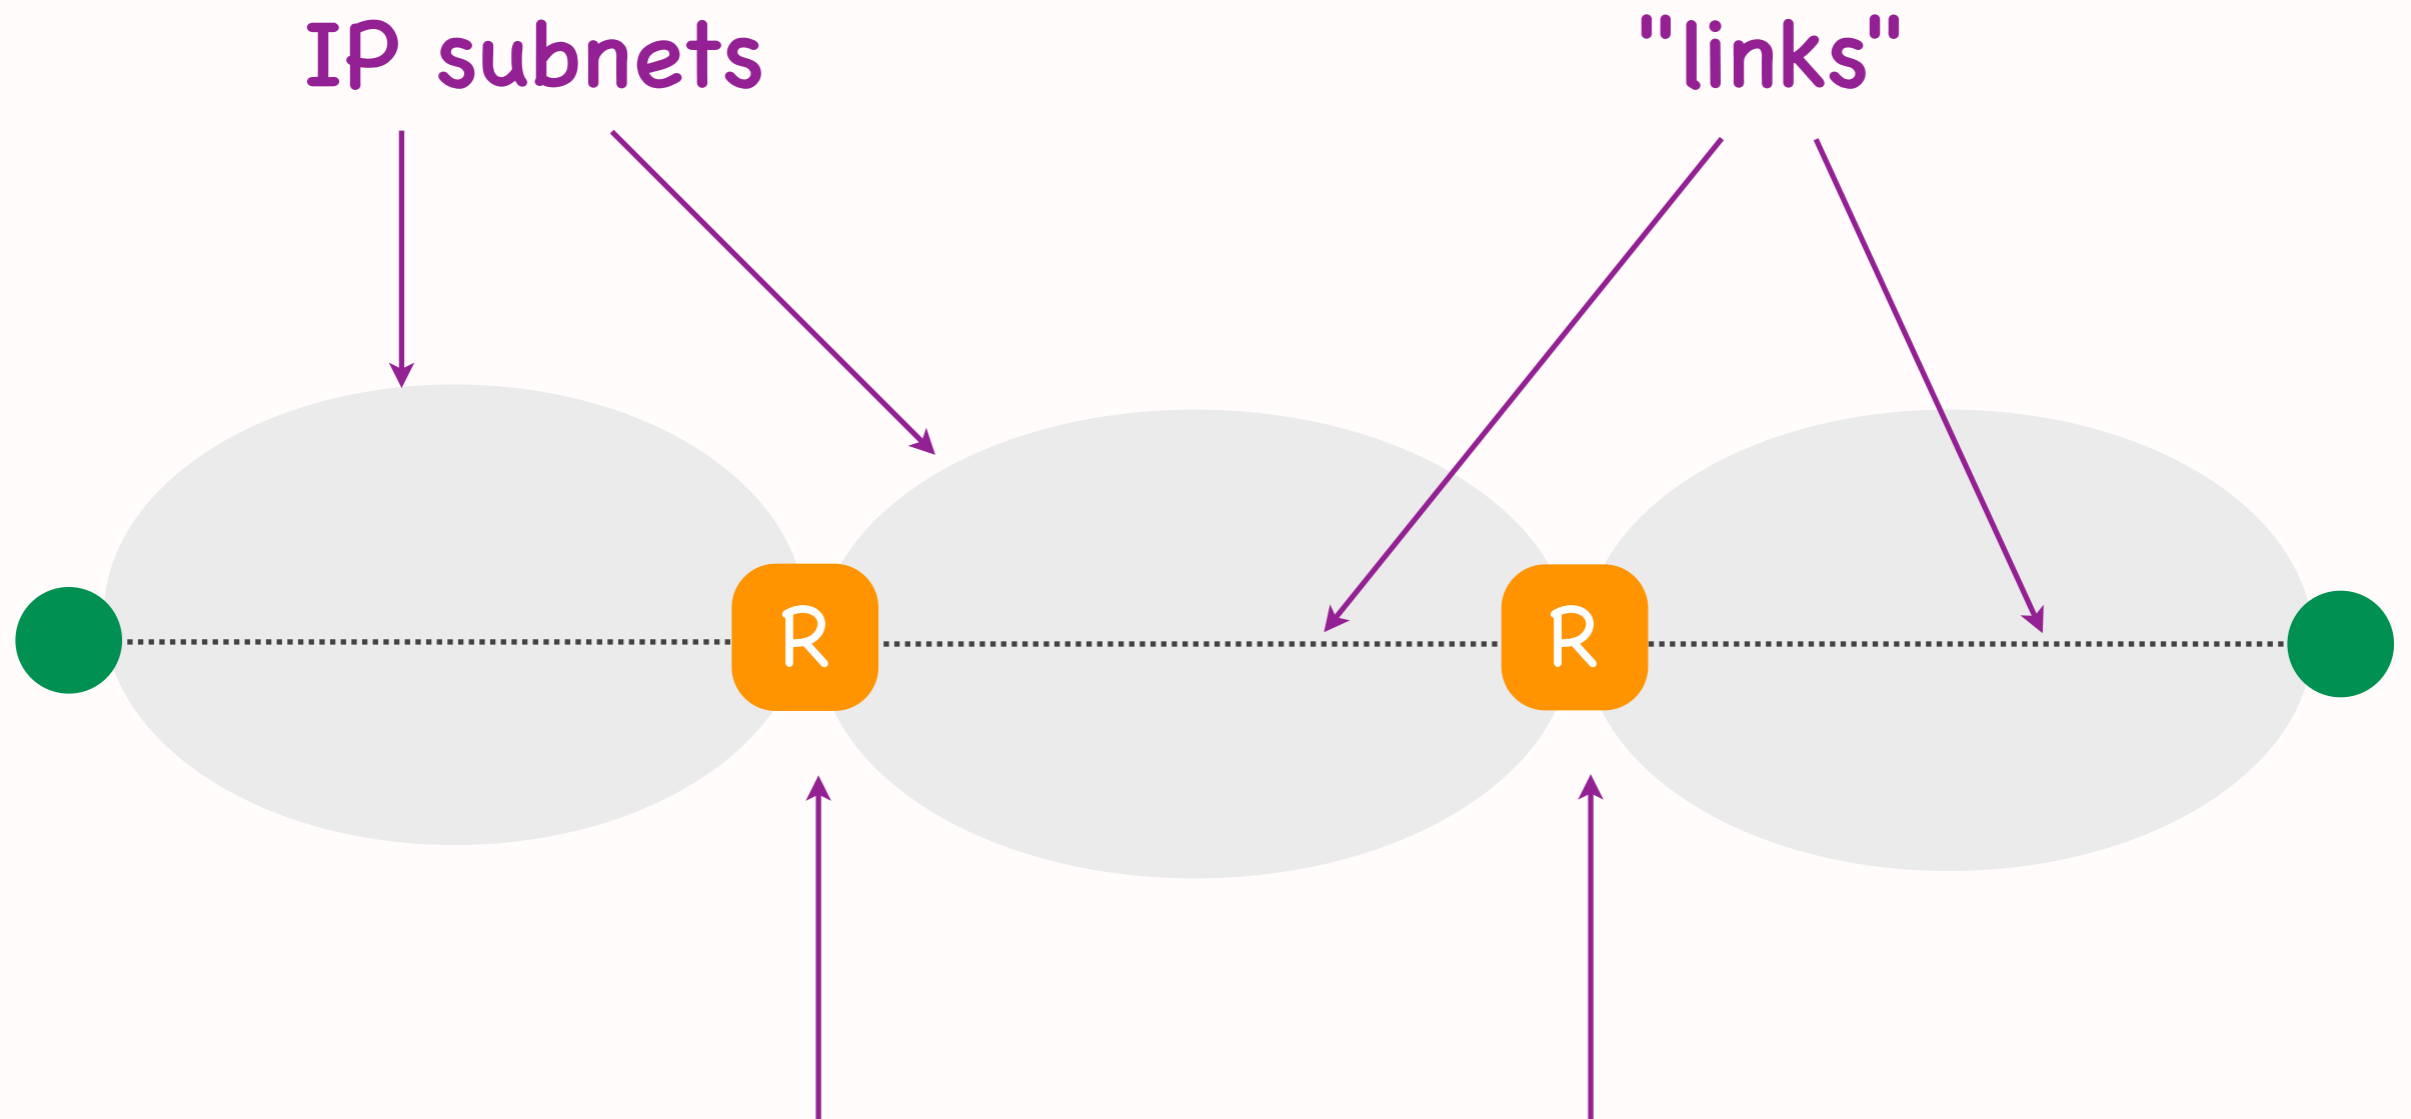

# Link vs. network layer

- Link layer: takes each packet from one end of **one link** to the other end
- Network layer: takes each packet from one end of **the network** to the other end

# IP subnet point of view

- Link layer: takes packet from one end of **one physical link** to the other end
- Network layer: takes packet from one end of **the IP subnet** to the other end

IP routers = network-layer switches

# Internet point of view

- Link layer: takes packet from one end of **one IP subnet** to the other end
- Network layer: takes packet from one end of **the Internet** to the other end

# The “link layer”

- Link layer **of an IP subnet**: takes packet from one end of **one physical link** to the other end
- Link layer **of the Internet**: takes packet from one end of **one IP subnet** to the other end

# The “link layer”

- Link layer of an IP subnet: takes packet from one end of one physical link to the other end
- Link layer of the Internet: takes packet from one end of one IP subnet to the other end

# Link-layer services

- Error detection
  - \* receiver detects and drops corrupted packets
  - \* relies on checksums
- Reliable data delivery
  - \* sender/receiver detect corruption and loss, and try to recover
  - \* relies on checksums, ACKs, retransmissions, ...
  - \* only for error-prone links, typically wireless

# Link-layer services

- Medium access control (MAC)
  - \* sender manages access to shared medium (typically wireless link)
  - \* listens for ongoing transmissions or "collisions"
  - \* backs off and retries later

Why reliable data delivery at the link layer?  
The transport layer does that anyway.

# The “link layer”

- Link layer of an IP subnet: takes packet from one end of one physical link to the other end
- Link layer **of the Internet**: takes packet from one end of **one IP subnet** to the other end

# Outline

- Addressing
- Forwarding
- Learning
- Address resolution

# Outline

- Addressing
- Forwarding
- Learning
- Address resolution

# MAC address

- 48-bit number
  - \* typical format: 1A-2B-DD-78-CF-CC
  - \* the value of each byte as hexadecimal
- Flat
  - \* not hierarchical like IP address
  - \* not location dependent

# Outline

- Addressing
- Forwarding
- Learning
- Address resolution

MAC address	link
5c:f9:38:a4:00:76	a
ab:ff:4d:a4:bb:af	b
...	...

`5c:f9:38:a4:00:76`

`ab:ff:4d:a4:bb:af`

# L2 forwarding

- Local switch process that determines output link for each packet
- Relies on forwarding table
  - \* maps destination MAC addresses to output links
- Similar to IP (L3) forwarding, except...

# MAC address

- Flat
  - \* not hierarchical like IP addresses
  - \* not location dependent

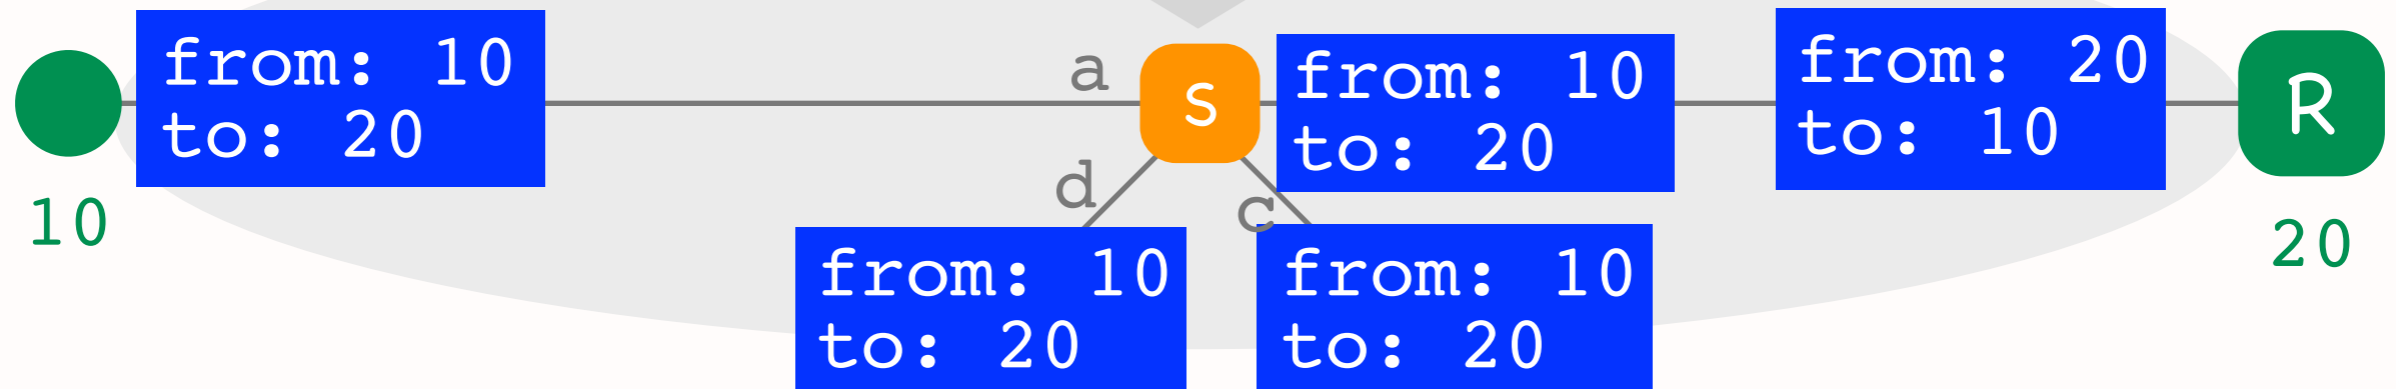

# L2 vs. IP forwarding

- L2: relies on flat addresses
  - \* no way to group MAC addresses in prefixes
  - \* forwarding table size = # of active destination MAC addresses in the IP subnet
- IP (L3): relies on hierarchical addresses
  - \* IP addresses grouped in IP prefixes
  - \* forwarding table size = # of IP prefixes in the world

# Outline

- Addressing
- Forwarding
- Learning
- Address resolution

MAC address	link
10	a
20	b

# L2 learning

- Switch learns from traffic
  - \* when packet with src MAC  $x$  arrives at link  $y$ , switch adds  $\text{MAC } x \rightarrow \text{link } y$  mapping to forwarding table
- Broadcasts when it does not know
  - \* when packet with unknown dst MAC arrives, switch broadcasts the packet
- Serves similar role as IP routing, but...

# L2 learning vs. IP routing

- L2 learning: relies on actual traffic
  - \* switches do not exchange explicit routing information
- IP routing: relies on routing protocol
  - \* routers exchange explicit routing messages

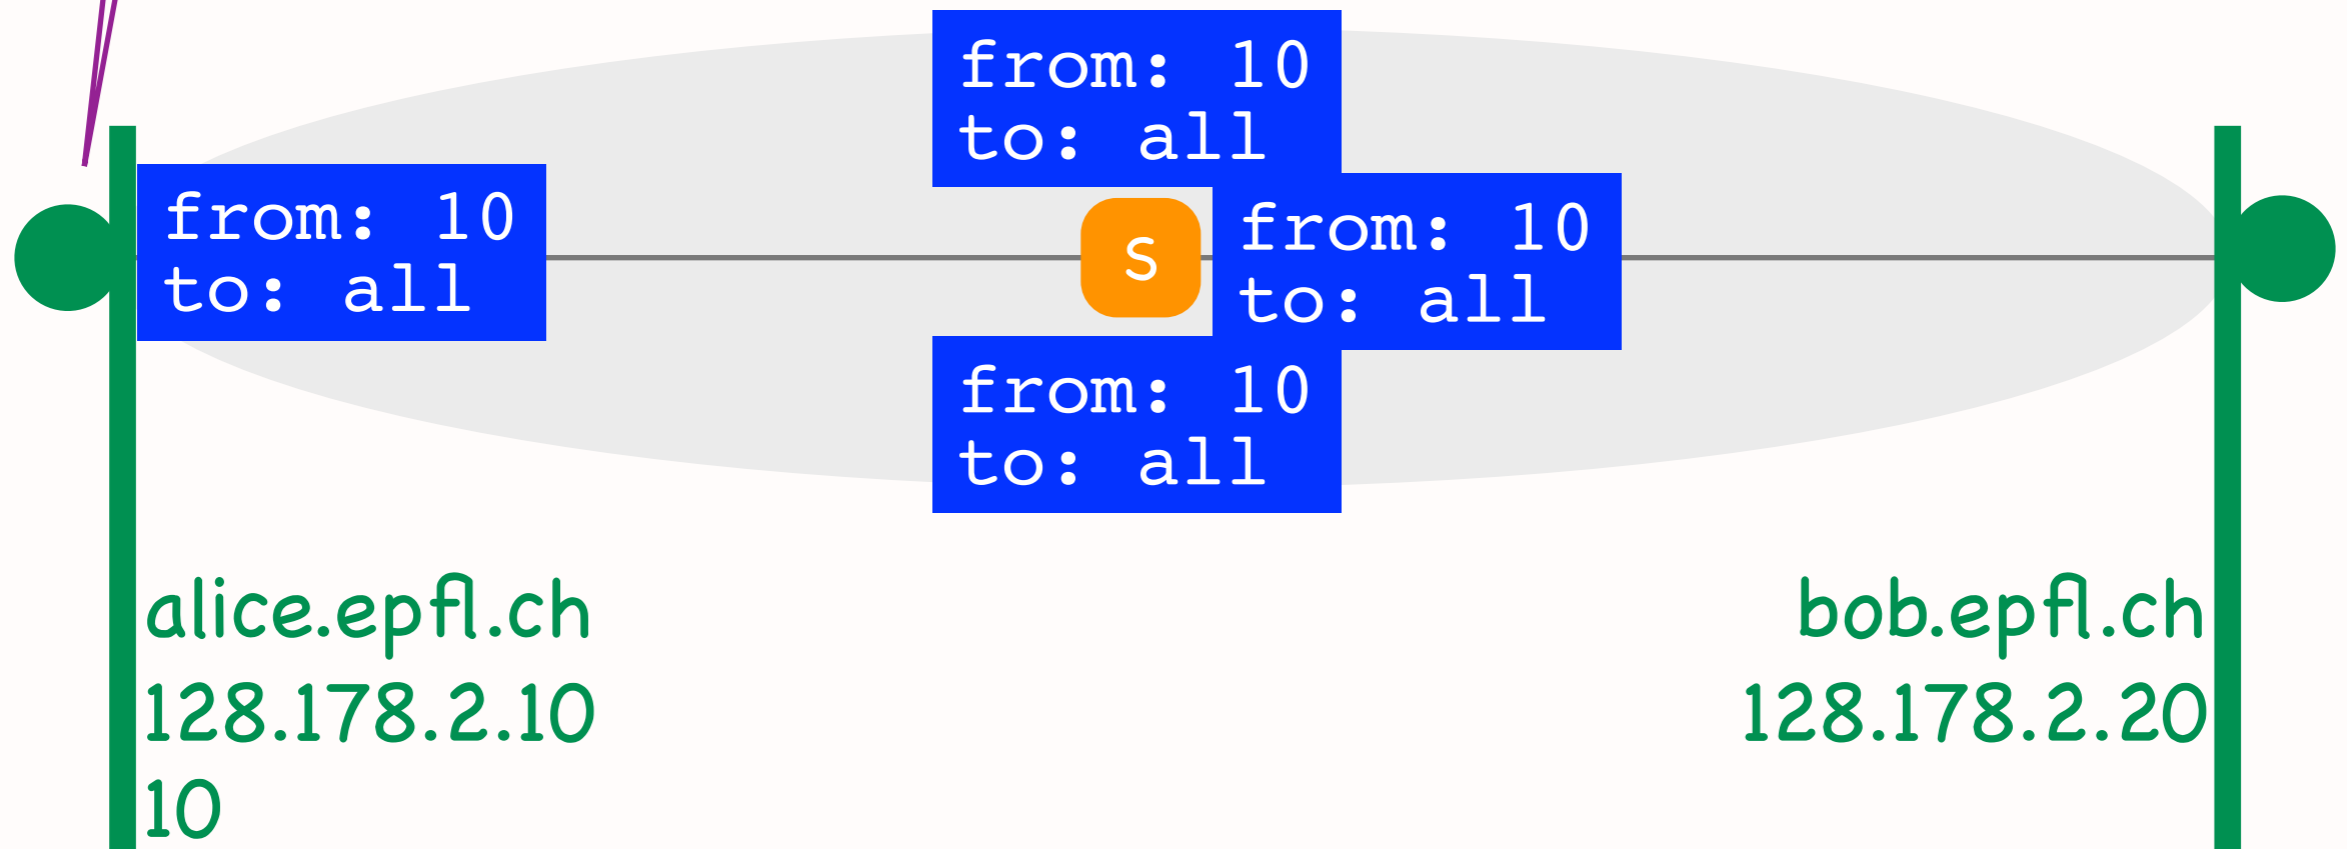

naïve broadcasting = forwarding loops!

# Outline

- Addressing
- Forwarding
- Learning
- Address resolution

I want to send a packet to IP address 128.178.2.20.  
Which destination MAC address should I use?

I want to send a packet to IP address 128.178.2.20.  
Which destination MAC address should I use?

Use my MAC address! It is 20.

I want to send a packet to IP address 104.20.228.42.  
Which destination MAC address should I use?

I want to send a packet to IP address 104.20.228.42.  
Which destination MAC address should I use?

Use my MAC address! It's 20.

My default gateway has IP address 128.178.2.1.  
Which is its MAC address?

My default gateway has IP address 128.178.2.1.  
Which is its MAC address?

That's me. It's 20.

# Address Resolution Protocol (ARP)

- Goal: map IP address to MAC address
  - \* Alice knows destination IP address
  - \* which destination MAC address to use?
- How: broadcast request, targeted response
  - \* Alice broadcasts her request
  - \* the right entity responds to Alice
- Serves similar role as DNS, but...

# Broadcasting

- Alice sends request to special, broadcast destination MAC address
  - \* FF-FF-FF-FF-FF-FF
- Reaches every end-system and router in the local IP subnet

# ARP vs. DNS

- ARP: relies on broadcasting
  - \* no logically centralized map
  - \* each entity knows its own MAC address and knows which requests to respond to
- DNS: relies on DNS infrastructure
  - \* logically centralized map
  - \* stored in DNS servers

# Basic Ethernet elements

- Address Resolution Protocol
  - \* resolves IP address to MAC address
- L2 forwarding
  - \* based on MAC addresses (which are flat)
- L2 learning
  - \* populates switch forwarding table

# Basic Ethernet elements

- Address Resolution Protocol [rel. to DNS]
  - \* resolves IP address to MAC address
- L2 forwarding [rel. to IP forwarding]
  - \* based on MAC addresses (which are flat)
- L2 learning [rel. to IP routing]
  - \* populates switch forwarding table

Get rid of IP addresses and IP forwarding?

Get rid of MAC addresses and L2 forwarding?
