Fall 2021

Week 6

# Decentralized search / routing

---

- Unstructured: flooding, expanding-ring  $O(n)$   
Bubble Storm =  $O(\sqrt{n})$  per search  
 $O(n^2)$  overall  
 $O(n\sqrt{n})$  total
- 

- Structured: build up state about the network  
efficiency:  $O(\log n)$  per search  
 $O(n \log n)$  overall
- 

- Search: given name, ID, address/location - piece of information  
assumes lower-layer that "gets us there"

- Routing: given name, ID, address/location  
use to communicate w/ target  
find a path to target

Example search/routing:

- DHTs (search):

- Chord, Pastry, Kademlia (IPFS, Swarm, ...)  
BitTorrent, D2P

- (Compact) routing:

- Name-independent:  
search + routing

- Name-dependent:  
routing only

stretch 1  
non-compact:  $O(n)$  cost per node,  
 $O(n^2)$  overall

takes arbitrary names  
 $O(\sqrt{n})$  per node,  
stretch  $\leq 3$

algorithm assigns addresses  
 $O(\log n)$  state per node  
stretch  $\leq O(\log n)$

# DHT - Chord $O(\log n)$ ←

- Hash ID space:  $\text{HASH}(\text{name}) \rightarrow \text{HID}$   
 eg. SHA256 ID = 256-bit integer

increasing -  $2^{256}$  addr

5/8 B
1/8
1/4 C
1/2 A D

Uses hash IDs for:  
 - node IDs  
 - obj IDs

Object ID:  $\text{HASH}(\text{contents})$   
 Node ID:  $\text{HASH}(\text{pub key})$

$2^{255}$   
 $O(\log_2 n)$   
 filled (challenge)

random nonce  
 $\leftarrow \text{SIG}_B(\text{nonce}, \dots) \quad H(\text{pk}_B)$
