

Lecture 2:

# Introduction (part 2)

Katerina Argyraki, EPFL

■ Respect @ EPFL

# Safe Space

<https://go.epfl.ch/safespace>

# Last week

- Lab (basic networking tools)
- Firefox redirecting http to https
- VDI access for UNIL students
  - working on it

# This week

- **Fri, Oct. 1: lecture (finish introduction)**
- **Tue, Oct. 5: office hours (homework)**
- **Wed, Oct. 6: lab session  
(measuring Internet performance)**

# Questions

- What's underneath?

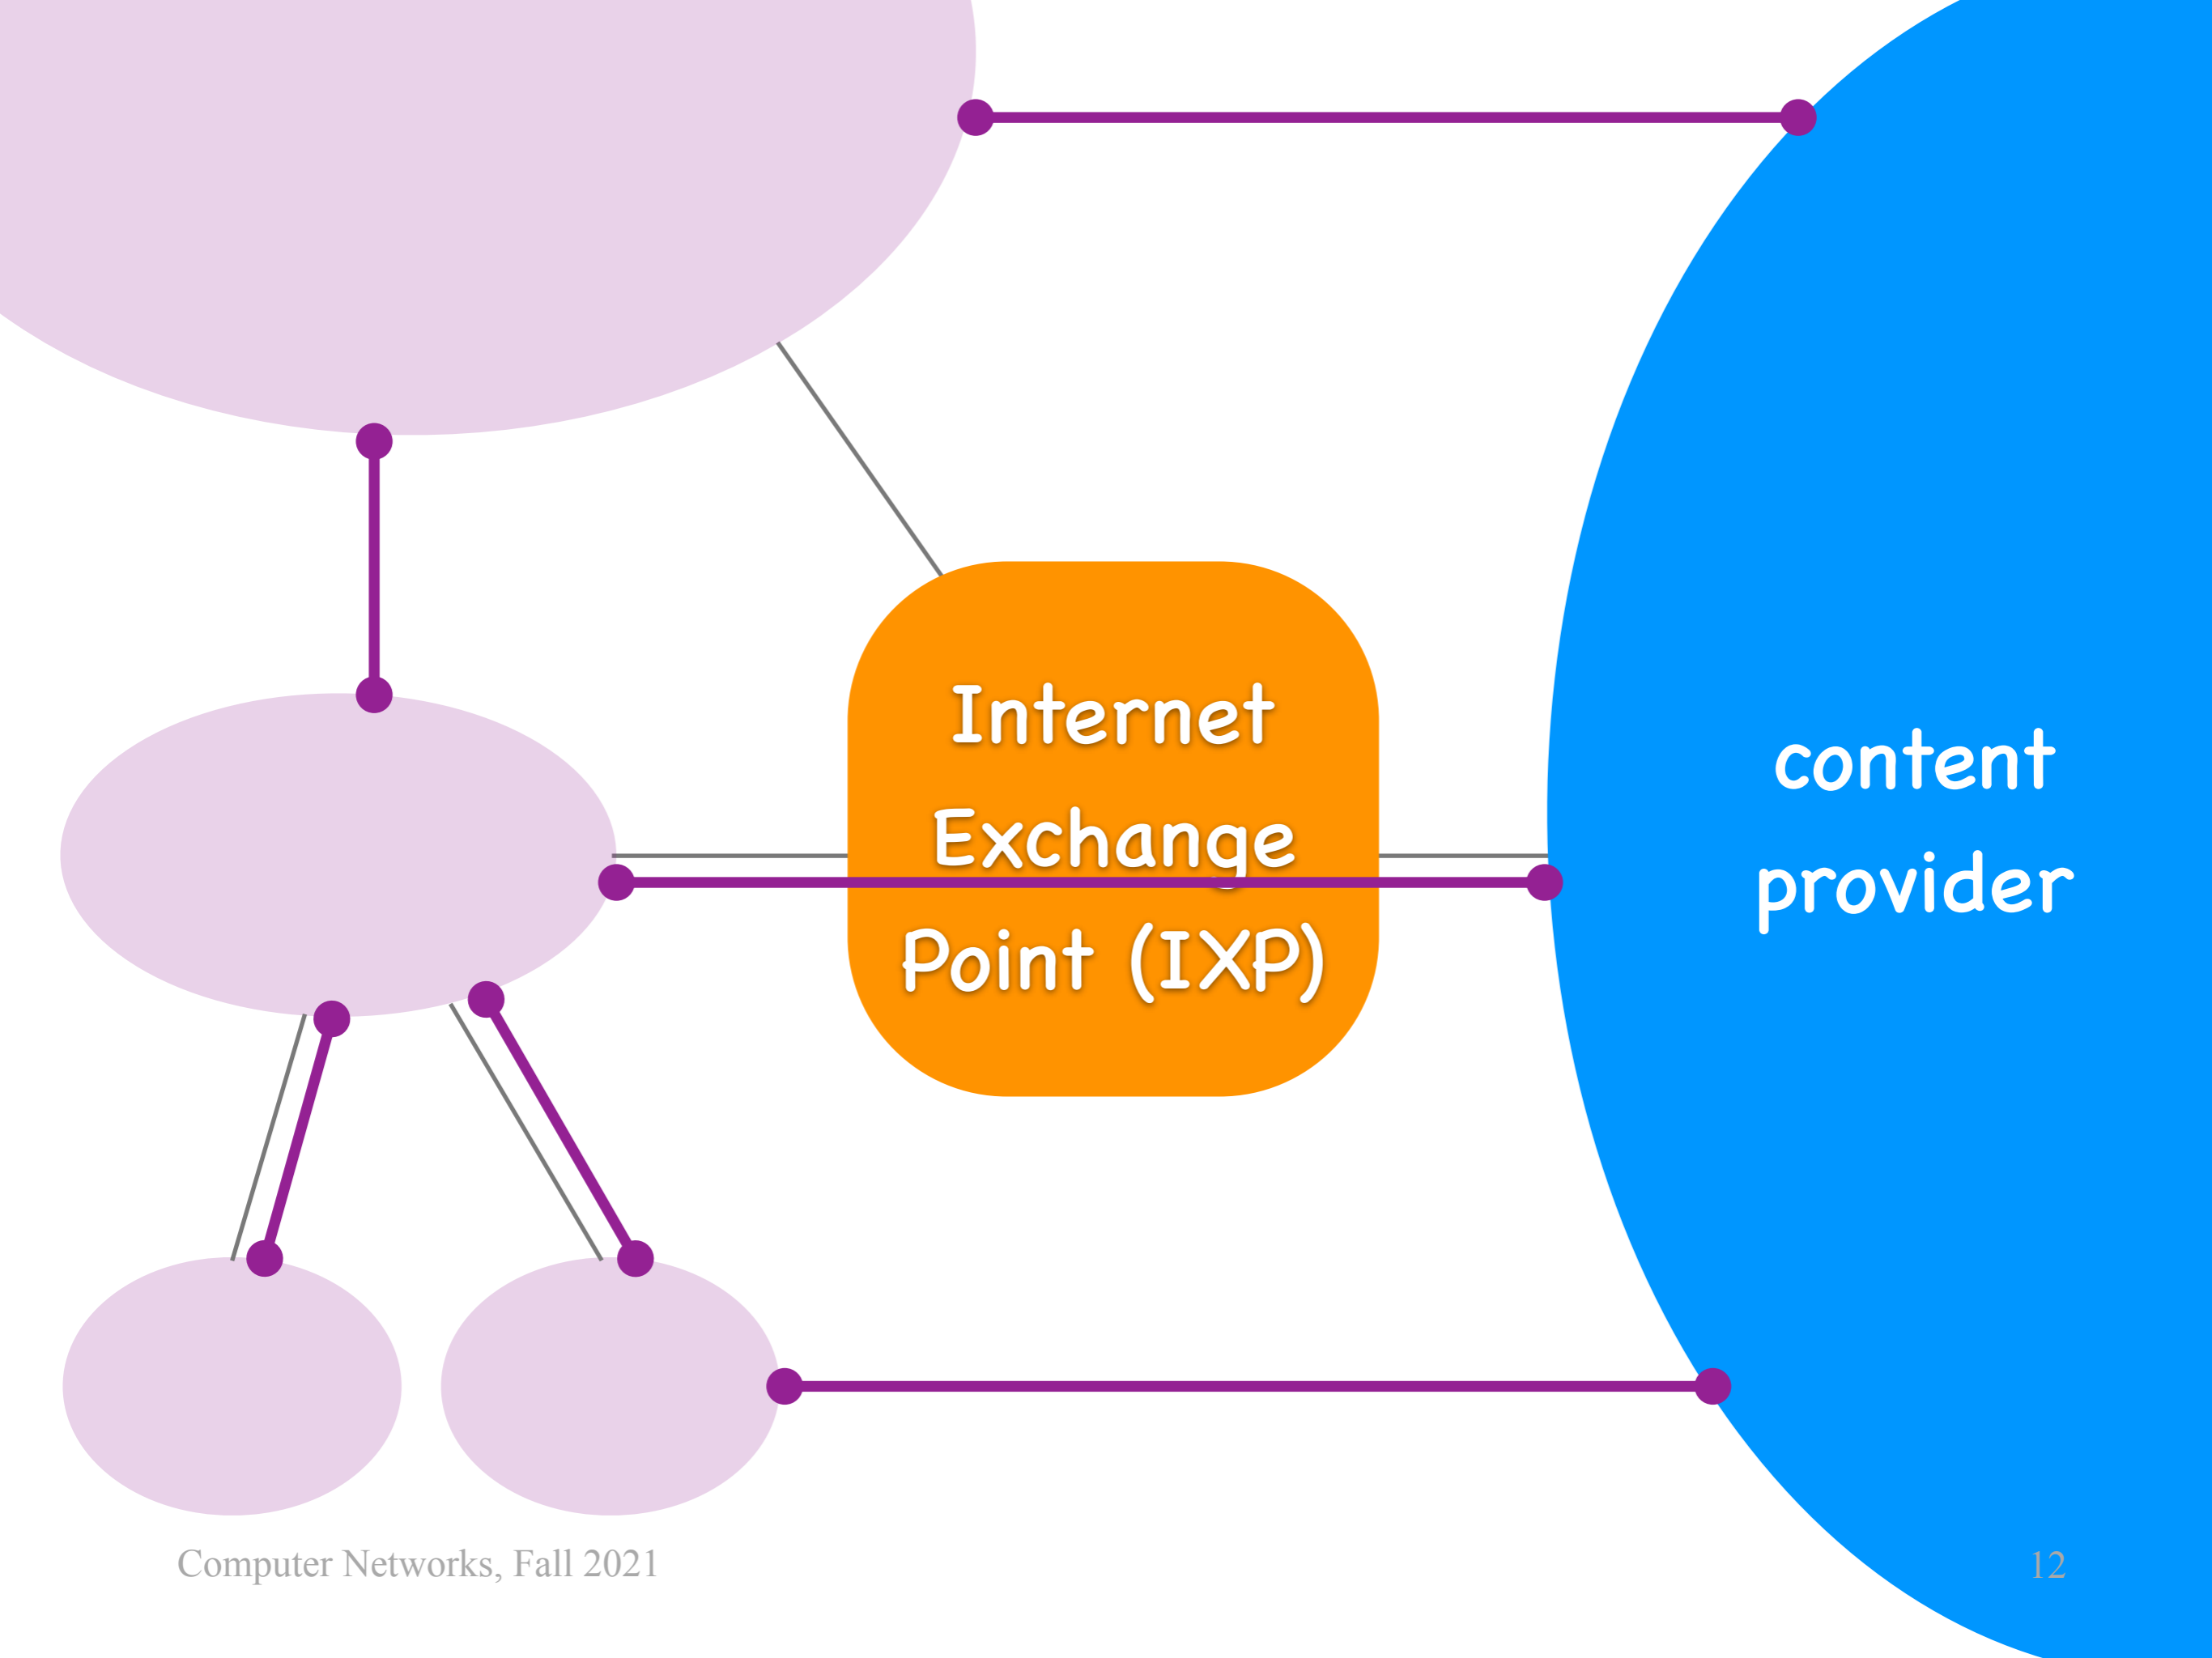

# Questions

- What's underneath?
- Who owns what?

# Questions

- What's underneath?
- Who owns what?
- How does it work?

# Questions

- What's underneath?
- Who owns what?
- How does it work?
- **How does one evaluate it?**
- How do end-systems share it?

# Basic performance metrics

- Packet **loss**
  - the fraction of packets from src to dst that are lost on the way
  - in %, e.g., 1% packet loss
- Packet **delay**
  - the time it takes for a packet to get from src to dst
  - in time units, e.g., 10 msec

# Basic performance metrics

- **Average throughput**
  - the average rate at which dst receives data
  - in bits per second (bps)
  - e.g., dst receives 1 GB of data in 1 min;  
average throughput =  $8 \cdot 10^9 \text{ bits} / 60 \text{ sec} = 133.34 \cdot 10^6 \text{ bps} = 133.34 \text{ Mbps}$

# Delay vs. throughput

- Packet **delay** matters for **small** messages
- Average **throughput** matters for **bulk** transfers
- They are related to each other, but not in an obvious way

transmission delay

$$= \frac{\text{packet size}}{\text{link transmission rate}}$$

$$= \frac{3 \text{ bits}}{1 \text{ Gbps}} = 3 \text{ nsec}$$

src

dst

propagation delay

$$= \frac{\text{link length}}{\text{link propagation speed}}$$

$$= \frac{1 \text{ meter}}{3 \cdot 10^8 \text{ meters per sec}} = 3.34 \text{ nsec}$$

src

dst

packet delay =  
transmission delay  
+ propagation delay

# circuit switch

packet delay =

transmission delay over 1st link  
+ propagation delay of 1st + 2nd link  
(+ delay to establish circuit,  
amortized over multiple packets)

# store & forward switch

packet delay =

transmission delay over 1st link  
+ propagation delay of 1st link

# store & forward switch

packet delay =

transmission delay over 1st link

+ propagation delay of 1st link

+ queuing delay

+ processing delay

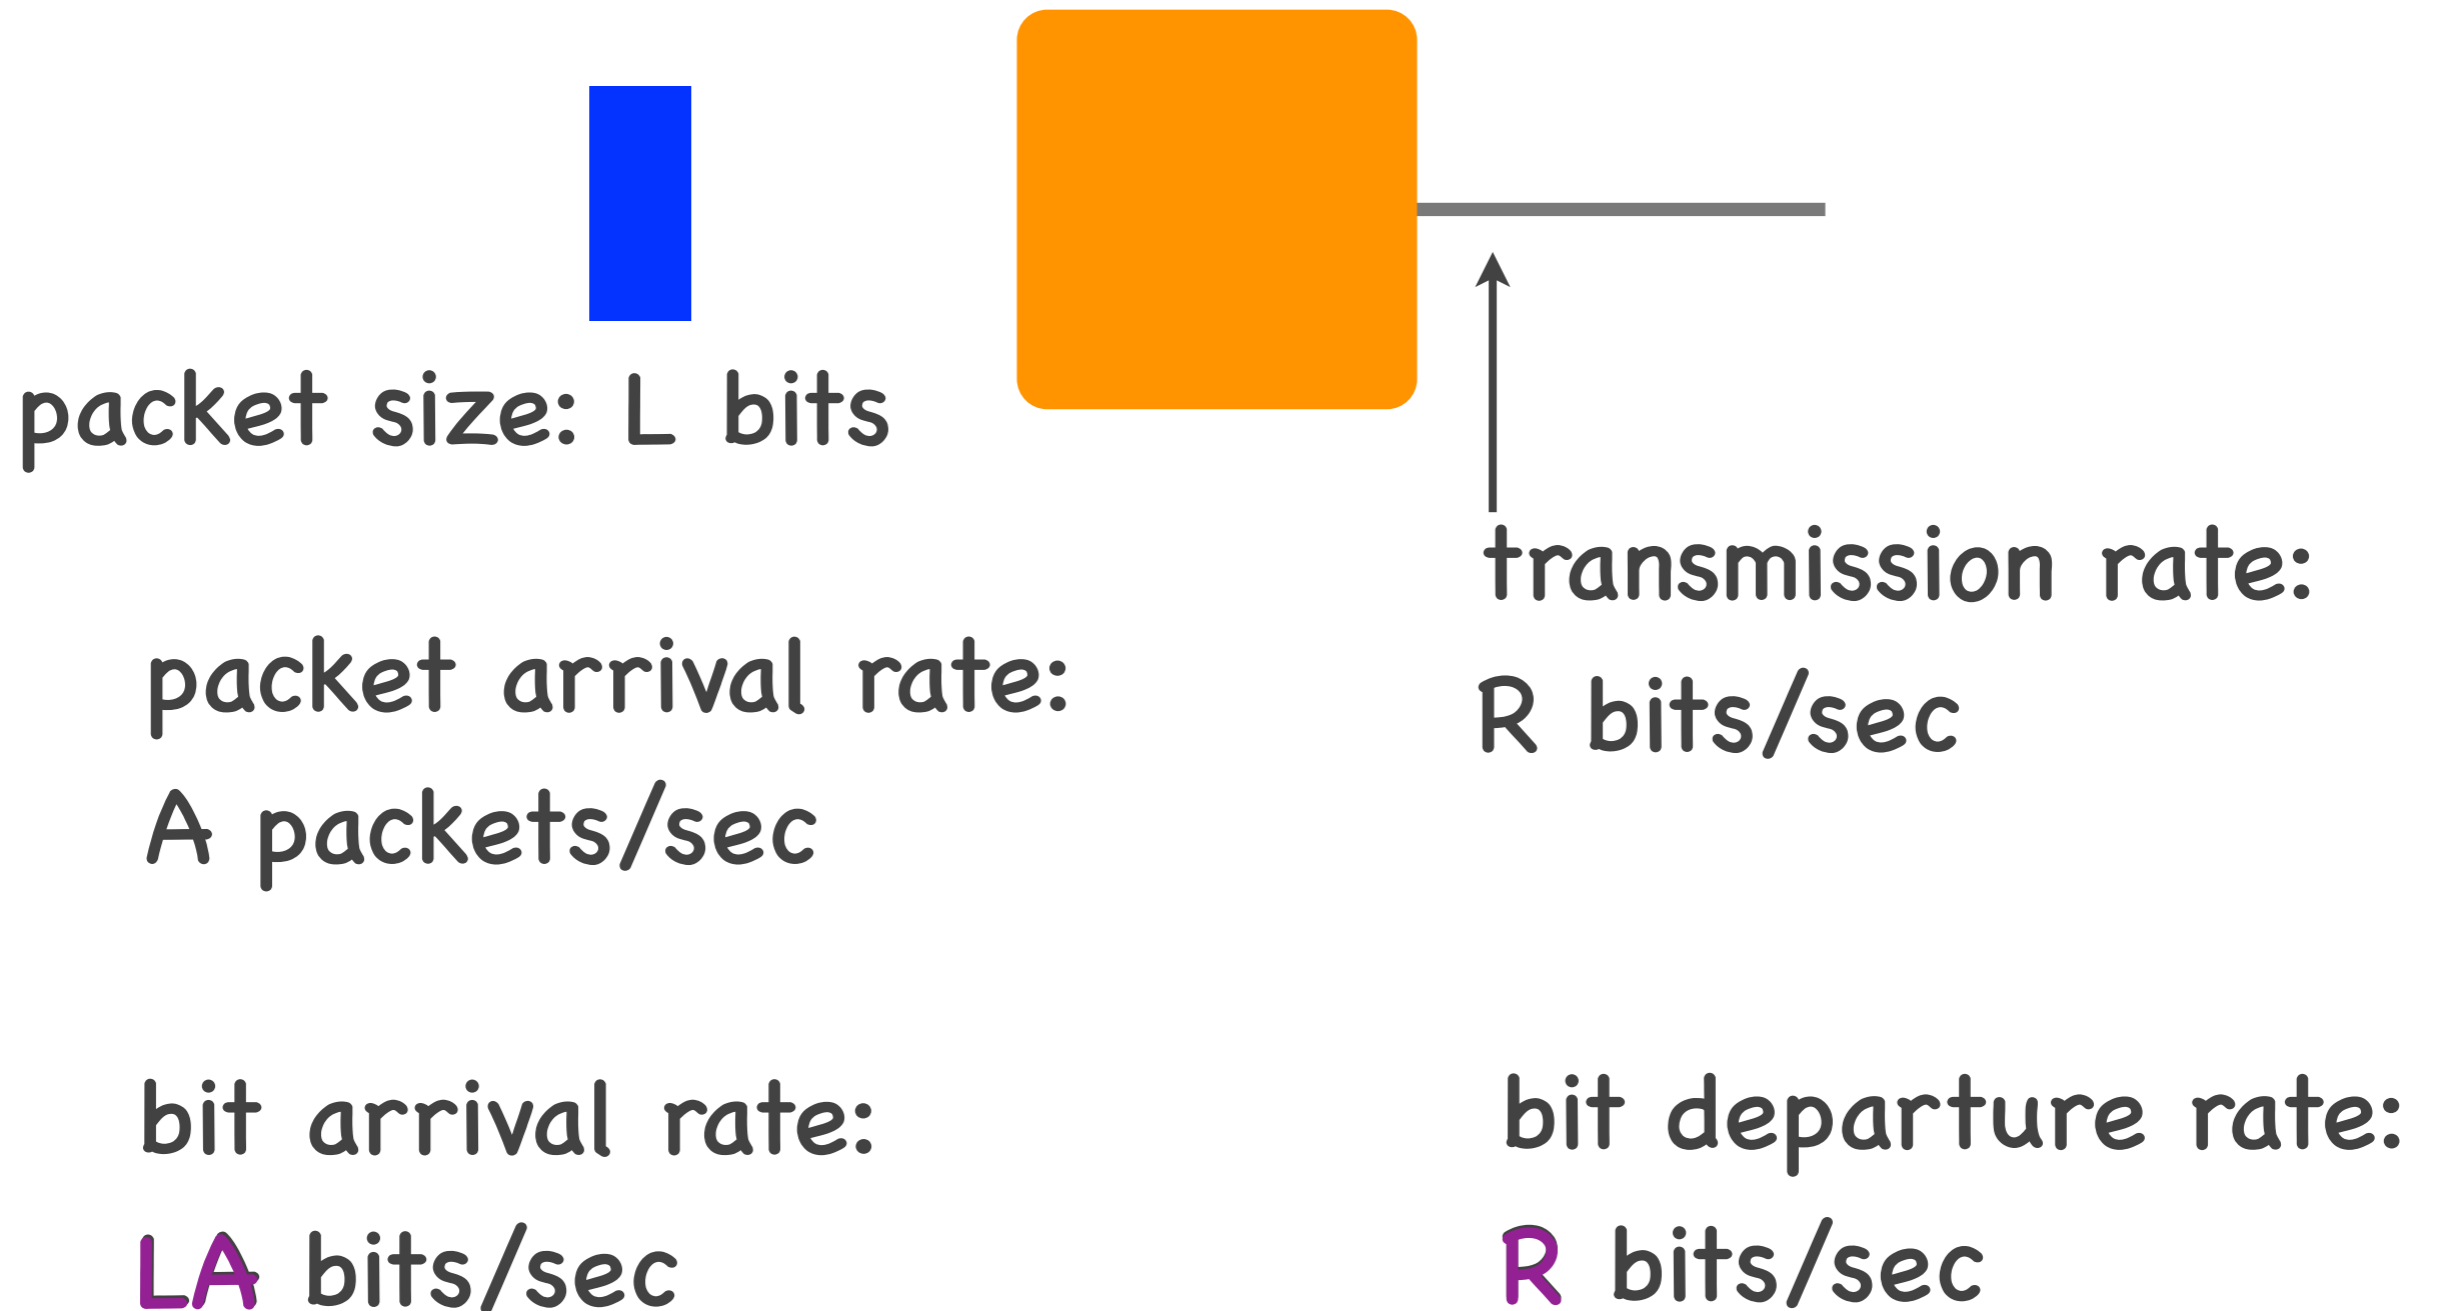

+ transmission delay over 2nd link

+ propagation delay of 2nd link

# Queuing delay

- Given info on **traffic pattern**
  - arrival rate at the queue
  - nature of arriving traffic (bursty or not?)
- Characterized with **statistical** measures
  - average queuing delay
  - variance of queuing delay
  - probability that it exceeds a certain value

bit arrival rate:  
 $\lambda$  bits/sec

bit departure rate:  
 $R$  bits/sec

# Queuing delay

- (Assuming infinite queue)
- Approaches **infinity**,  
if arrival rate  $>$  departure rate

bit arrival rate:  
 $\lambda$  bits/sec

bit departure rate:  
 $\mu$  bits/sec

0 usec  
1 usec  
2 usec  
3 usec

bit arrival rate:  
 $L$  bits/sec

$\leftarrow =$

bit departure rate:  
 $R$  bits/sec

# Queuing delay

- (Assuming infinite queue)
- Approaches **infinity**,  
if arrival rate  $>$  departure rate
- Depends on **burst size**, otherwise

Queuing delay upper bound:  $N L/R$

# Packet delay

- Many components: **transmission, propagation, queuing, processing**
- Depends on network topology, link properties, switch operation, queue capacity, other traffic

transmission rate  $R$  bits/sec

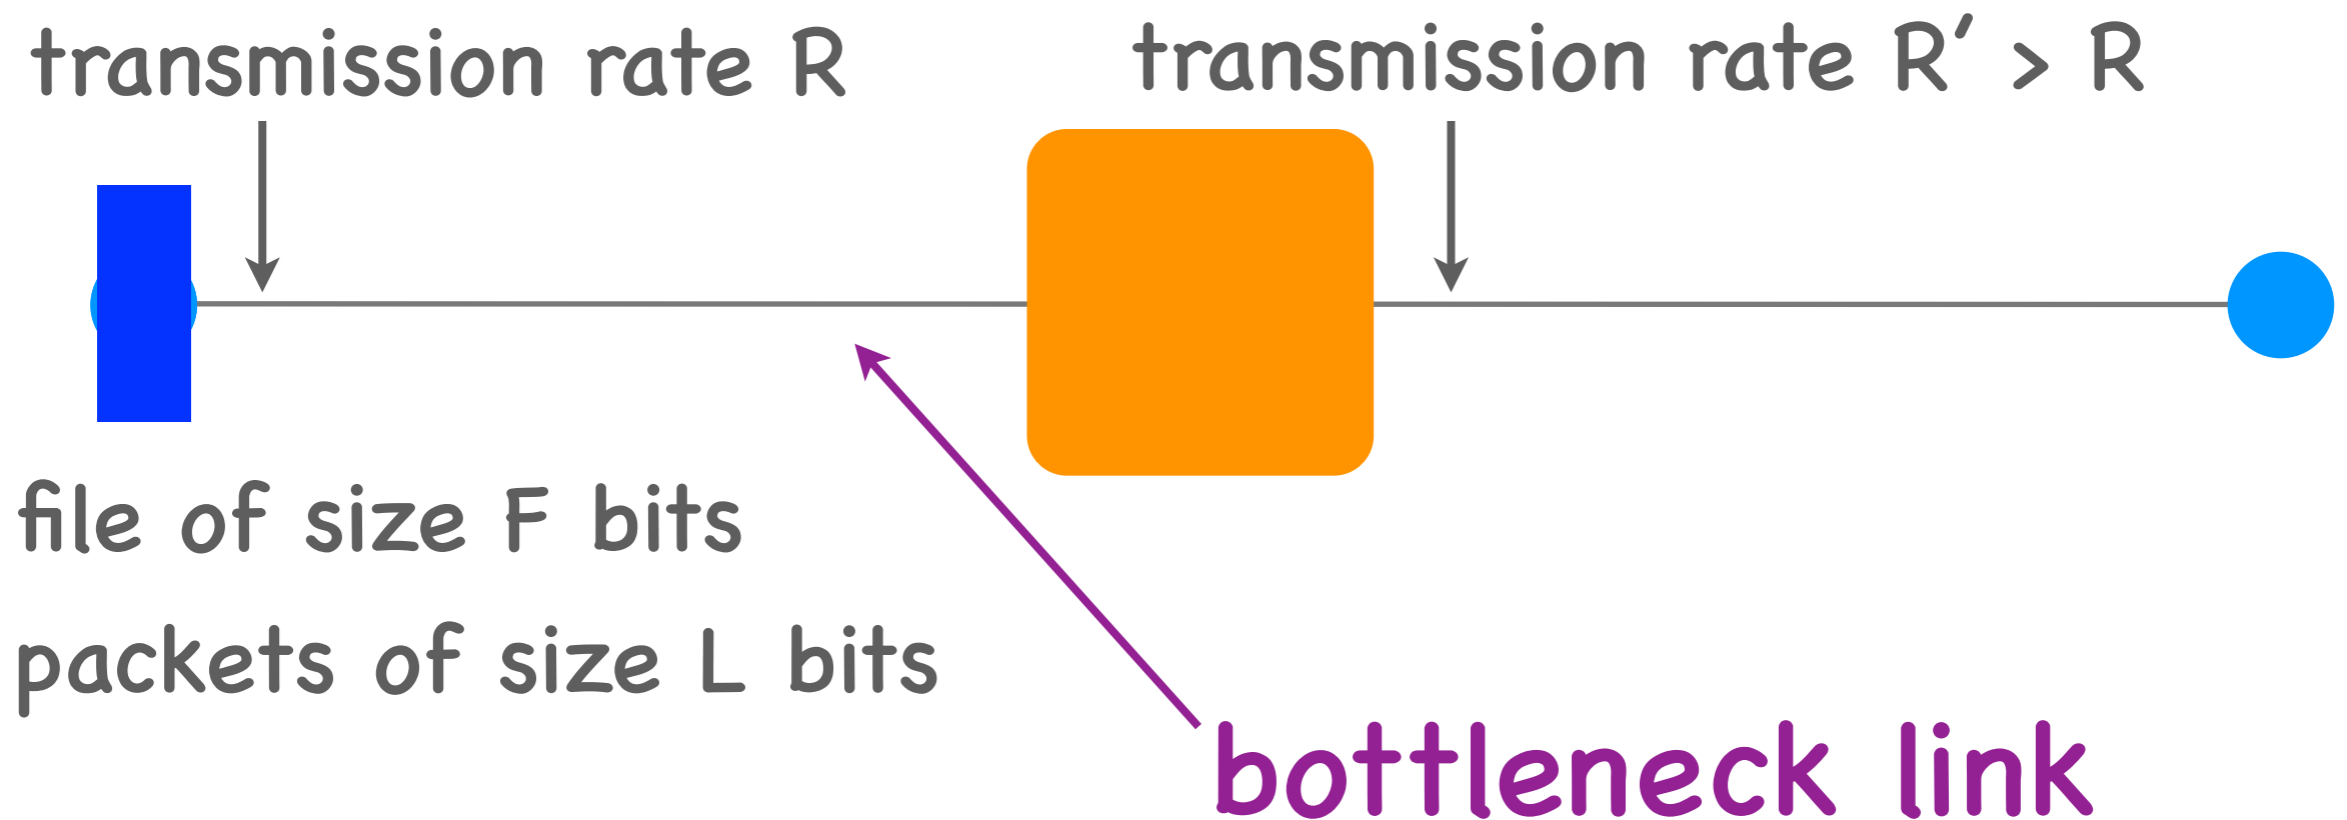

file of size  $F$  bits

packets of size  $L$  bits

Transfer time =  $F/R$  + propagation delay

Average throughput =  $R$

Transfer time =  $F/R$  + propagation delay 1st link  
 +  $L/R'$  + propagation delay 2nd link

Average throughput =  $\min \{ R, R' \} = R$

transmission rate  $R \gg R_1, R_2$

transmission rate  $R_1$

transmission rate  $R_2$

**bottleneck link**

# Bottleneck link

- The link where traffic flows at the **slowest** rate
- Could be because of the link's transmission rate or because of queuing delay

# Questions

- What's underneath?
- Who owns what?
- How does it work?
- How does one evaluate it?
- **How do end-systems share it?**

# Switch contents

- **Queue**
  - stores packets
- **Forwarding table**
  - store meta-data
  - indicate where to send each packet

packet loss

queuing delay

# Packet switching

Packets treated on demand

# “Connection switching”

Resources reserved in advance

# Resource management

- Packet switching
  - packets treated **on demand**
  - admission control & forwarding decision:  
per packet
- “Connection switching”
  - resources **reserved** per active connection
  - admission control & forwarding decision:  
per connection

**Treat on demand or reserve?**

# “Connection switching”

Predictable performance

# “Connection switching”

Inefficient use of resources

# Packet switching

# Packet switching

Efficient use of resources

# Packet switching

Unpredictable performance

# Packet switching

**We need congestion control**

# Resource management

- Packet switching
  - **efficient** resource use
  - no performance guarantees
  - simpler to implement,  
but requires **congestion control**
- “Connection switching”
  - performance **guarantees**
  - inefficient resource use

Each user is active w.p. 10%

With 35 users, 10 or fewer users are active w.p. 99.96%

Connection switching: 10 users  
Packet switching: about 35 users

# Statistical multiplexing

- Many users share the same resource
- Not all of them can share it at the same time...
- but we do not expect them to be all active at the same time

Only 1 user active

Downloading a 10 Gbit video file

Connection switching: 10 seconds

Packet switching: 1 second

# Circuit switching

Connection switching  
through physical circuits

# Many kinds of “circuits”

- **Physical** circuits
  - separate sequence of physical links per connection
- **Virtual** circuits
  - manage resources **as if there was** a separate sequence of physical links per connection

# Many kinds of “circuits”

- **Time** division multiplexing
  - divide time in time slots
  - separate time slot per connection
- **Frequency** division multiplexing
  - divide frequency spectrum in frequency bands
  - separate frequency band per connection

# Many kinds of “circuits”

- Different ways to implement “connection switching”
- Create the **illusion** of a separate physical circuit per connection

**Treat on demand or take reservations?**

Alice

Bob

Eve (the eavesdropper)

tries to listen in on the communication,  
i.e., obtain copies of the data

Alice

Bob

Persa (the impersonator)

pretends that she is Alice to extract  
information from Bob

Alice

Bob

Denis (the denial-of-service attacker)

disrupts the communication  
between Alice and Bob

distributed denial-of-service attack

disrupts the communication  
between Alice and Bob

Alice

Bob

Malik (the malware master)

infects Alice and/or Bob

with malware = bad software

# Internet vulnerabilities

- Eavesdropping (sniffing)
- Impersonation (spoofing)
- Denial of service (dos-ing)
- Malware

What trust model to design for?

What physical infrastructure is already available?

What modularity & hierarchy?

What layers to define?

Treat on demand or take reservations?

What trust model to design for?
