# TCP/IP NETWORKING

## LAB EXERCISES (TP) 4

### DYNAMIC ROUTING (OSPF) AND SDN BASICS

#### With Solutions

---

November 17th, 2022  
**Deadline:** November 30th, 2022 at 23.59 PM

## 1 LAB ORGANIZATION AND INSTRUCTIONS

In this lab, you will learn how to configure the OSPF routing protocol, which typically runs inside the network of an autonomous system (AS). The protocol automatically sets up network routes that ensure shortest path between two points in the network with respect to a predefined metric (such as number of hops). You will configure a fully functional network using “Cisco-like” **emulated** routers. You will learn how to configure a network of routers. Optionally (bonus exercise), you can learn about software-defined networking (SDN) and study how it can be used to create forwarding rules on switches. You are strongly advised to do this part as it gives you a good idea of how enterprise networks are managed today.

For this lab, you will be using the same Mininet on the virtual machine provided on Moodle (see Lab 0 for installation instructions if need be).

The lab is meant to be done sequentially. Random access might give you different answers. We advise you to do a section in one sitting. Restarting Mininet within a section might make the analysis difficult. Finally, if you are copying commands into your terminal from this pdf, make sure that the copied string is still a valid command: especially, be wary of the *underscore* and *newline* characters.

## 2 FRRROUTING: SOFTWARE ROUTING SUITE

The Internet core is run by powerful routers that can handle large amounts of traffic and are built by companies such as Cisco, Huawei, or Juniper. Even in a large company, or in large university campuses (such as EPFL), these routers are present. They use proprietary operating systems (such as Cisco IOS, or JunOS) and can be accessed via control terminals tailored for network configuration, with commands that are quite different from those you may encounter in a UNIX/Linux console. In this lab and in lab 6, we will give you a flavour of router configuration.

Ideally, we would have liked to run Cisco IOS in a virtual environment. It is technically possible but not legal, as Cisco or Juniper do not allow their OSs to be run on a device other than their routers. Therefore,

we will use FRR, a free software that implements and manages various IPv4 and IPv6 routing protocols. It accepts similar commands to the ones in Cisco's IOS.

## 2.1 WHAT IS FRR AND HOW DOES IT WORK?

FRR is a routing software suite that provides implementations of several routing protocols (namely OSPF, RIP, and BGP-4) for Unix platforms. The architecture of FRR is shown in Figure 1.

Figure 1: FRR Architecture

As depicted in the figure, it consists of a handful of processes that can be run in the background as daemons. Three FRR processes (daemons) are important for executing this lab:

- *zebra*: is used to manage the network interfaces of a machine (in our case, each router will run in the virtual machine). It allows you to configure them (using IPv4 and/or IPv6 addresses), to monitor their states, and it provides a more detailed view of the routing tables than the `route -n` command. In a way, *zebra* is a replacement for the Linux networking commands used during the first three labs (*i.e.*, `ifconfig`, `route`, etc.).
- *ospf*: handles OSPF version 2 implementation.
- *ospf6d*: handles OSPF routing for IPv6.

## 3 SCENARIO: A GAME OF ROUTERS

With the impending attack of the White Walkers on Westeros, all the kingdoms must unite in the fight for the living. As the lands of men stretch from Winterfell in the North to Valyria down in the South, the wise maesters at the Citadel have realized that their communication network with carrier ravens will not be sufficient to communicate for large distances in short time.

After several sleepless nights in the Citadel, Maester Illyrio Pycell and his intern Samwell Tarly have designed the communication mechanism, called TCP/IP. Together, they setup routers and switches at strategic locations in Westeros as shown in Figure 2. There are a total of 5 routers `r1-r5` placed at Winterfell, Braavos, Valyria, Casterly Rock, and King's Landing, respectively. Samwell has connected the routers through 7 switches as shown in the figure. He has also configured the routers with the IP addresses as shown in the figure. Note that all IP Addresses for router `rx` end in `x`.

Sam's configuration scripts are available in the lab folder. To be consistent with the paths in this document and in the scripts, please place the uncompressed folder directly in the Desktop of the virtual machine and be sure to name it **lab4** (case-sensitive). Run `lab4_network.py` as root from a terminal of your virtual

Figure 2: Networking in Westeros

machine, to recreate the established topology. See the output of the `net` command in the Mininet prompt and verify whether the connections in the created network correspond to the ones of Figure 2. Use the `pingall` command in the mininet prompt.

#### Q1/ Answer to Lab 4 Part 1 Question 1 on Moodle

**Solution:** Percentage of lost packets: 78%

To reach a 100% success rate we need :

1. Routing configuration on all routers (dynamic or static)
2. Provide IP addresses to all router interfaces

*In our python script, we are only configuring/assigning one IP address per router and host. In the case of h1 and r1, we assigned the ip addresses that belong to the same LAN. We don't have other connectivities because we have not configured all the interfaces of different hosts and routers (except one interface at each host and router) and we have not enabled static or dynamic routing at the routers.*

In the next section, your job is to help Sam with the configuration of the network so that all kingdoms can talk to each other.

Each router is, in essence, a Linux machine, thus they can be configured the same way. This means that you

could reuse the same set of commands that you used for previous labs, e.g., to configure network interfaces, to monitor their states, to inspect the contents of the routing tables, etc. However, instead of the set of Linux networking commands, in this lab, you will be using the tool suite from *FRR*. Documentation can be found on the FRRouting website ([www.http://docs.frrouting.org](http://docs.frrouting.org)).

## 4 HOST NETWORK CONFIGURATION WITH FRR

In principle, you could create a topology without FRR, launch a terminal window for each router, and configure its network interfaces using the `ip addr` command (following the scheme shown in Figure 2). However, in this lab, we will be using the `zebra` daemon instead.

**Note:** Never try to configure the network interfaces on a machine using both the `ip addr` command and `zebra` daemon, as interaction between the two is not always clear and the outcome may be uncertain.

### 4.1 CONFIGURING INTERFACES USING CONFIGURATION FILES

Before running your topology script, a configuration file must be created and edited at least for the `zebra` process. Script 1 is an example of such a file written for router `r3`. This file can be found among setup files available on Moodle in the `lab4/configs` folder.

Script 1: Zebra configuration file for r3: `zebra_r3.cfg`

```
1 hostname r3
2 password zebra
3 enable password zebra
4
5 log file /home/lca2/Desktop/lab4/logs/zebra_r3.log
6 debug zebra packet
7
8 ip forwarding
9 ipv6 forwarding
10
11 interface r3-eth1
12 no shutdown
13 ip address 10.10.23.3/24
14 ipv6 address 2001:1:0:23::3/64
15
16 interface r3-eth2
17 no shutdown
18 ip address 10.10.35.3/24
19 ipv6 address 2001:1:0:35::3/64
```

Let's examine the content of this configuration file:

- `!`: the lines starting with `!` are comments, they are ignored;
- `enable password`: this creates a password for “on the fly” configuration of the `zebra` process, in this case the password is set to `zebra`;
- `log file`: Allows you to specify the file to which `zebra` related information is logged (adding, deleting routes in principle). **Make sure you write the full path to the file as it could prevent the FRR service from starting;**
- `debug zebra packet`: more detailed debugging, *i.e.*, allows you to see when routes are added or deleted from the routing table;
- `ip forwarding`: This instructs the `zebra` process to enable IPv4 routing on the router;
- `ipv6 forwarding`: This instructs the `zebra` process to enable IPv6 routing on the router;

- `interface <interface name>`: this command starts the interface configuration mode;
- `ip address`: assigns an IPv4 address to the selected interface;
- `ipv6 address`: assigns an IPv6 address to the selected interface;

We already created all the configuration scripts for the routers *r3*, *r4*, and *r5*, you can find them in the folder we provided. **You can now create the configuration scripts for the routers *r1* and *r2*.**

You should now have all the following files: `zebra_r1.cfg`, `zebra_r2.cfg`, `zebra_r3.cfg`, `zebra_r4.cfg`, `zebra_r5.cfg`. For consistency with the paths of the proposed commands and with the paths of the log files, it is highly recommended that you copy your `lab4` folder to your Desktop. This folder contains the `configs` folder, the topology script, an empty `logs` folder and an empty `run` folder. Each time you launch the simulation, the `logs` and `run` folders must be empty and the `configs` folder must contain only the `.cfg` files. The topology script erases the content of the `logs` and `run` before creating the topology. If you wish to stop the mininet simulation, type `exit` in the mininet prompt and clear the cache with the following command:

```
sudo mn -c.
```

Activate the zebra daemon at router *r1* with the following command:

```
zebra -d -f /home/lca2/Desktop/lab4/configs/zebra_r1.cfg -i
/home/lca2/Desktop/lab4/run/zebra_r1.pid
-z /home/lca2/Desktop/lab4/run/frr_r1.api -u root -k
```

Do the same for all routers.

This way, we have manually started the zebra daemon on each router. In order to prevent re-writing this command at each router at each simulation, we advise you to update the python script that creates the network topology `Lab4_network.py` in order to make the process start automatically at all routers. This can be done by updating the script with commands as such:

```
<routerID>.cmd(' <command>')
```

where `<routerID>` is *r1*, *r2*, *r3*, *r4* or *r5* and `<command>` is the command you would type on the router's terminal.

Check that zebra is running for all routers by checking the list of all running processes in the VM: you can do so with the following command: `ps -A`, if you wish to restrict the list to only zebra processes type the following: `ps -aux | grep zebra`. Observe that each process has a PID, if you wish to stop a process, the command is: `kill < PID >`. If you want to stop all zebra processes, you can do so with the following: `kill $(ps -aux | pgrep zebra)`, `pgrep` directly extracts the PIDs. Note that processes running for mininet entities such as *r1*, are in fact running on the VM, hence by terminating the mininet simulation, processes don't stop automatically. Make sure that you kill them all before launching new simulations, you can add this command in the script to be executed at the beginning of each new simulation.

#### 4.1.1 MONITORING MODE

In order to monitor the activity of a running process, e.g., `zebra`, you can enter the monitoring mode by connecting to it using the following command in the terminal of a router.

```
telnet localhost zebra
```

The password is zebra. Let us see what information can be obtained now. To inspect the contents of the IPv4 and IPv6 routing tables type `show ip route` and `show ipv6 route` respectively. At all times, you can view the entire list of the commands at your disposal using `list`.

## Q2/ Answer to Lab 4 Part 1 Question 2 on Moodle

### **Solution:**

*10.10.23.0/24*

*10.10.35.0/24*

*2001:1:0:23::/64*

*2001:1:0:35::/64*

*fe80::/64 (r3-eth1 link local)*

*fe80::/64 (r3-eth2 link local)*

*These are the same routes that you find if you do a ip route or ip -6 route commands from the linux terminal.*

Next, check the status of the network interfaces by typing `show interface` command.

To view the current running configuration, you need to first enable the configuration mode using

```
enable
```

The password for the configuration mode is zebra. Finally, inspect the running configuration of the router `r3` using the `show running-config` command and verify if it is the same as the one you used.

## 4.2 CONFIGURING OSPF

The `ospfd` process implements OSPFv2 that is defined in RFC 2328. Similar to the `zebra` process, the `ospfd` process can be configured by editing a configuration file or “on the fly”. However, in this lab, we will not configure it “on the fly”. Like the `zebra` configuration files, we are providing the “ready-to-use” `ospfd_r1.cfg`, `i=3,4,5` configuration files. We give an example of `ospfd_r3.cfg` configuration file in Script 2.

Script 2: Ospf configuration file for r3: `ospfd_r3.cfg`

```
1 hostname r3
2 password ospfd
3 enable password ospfd
4
5 log file /home/lca2/Desktop/lab4/logs/ospfd_r3.log
6
7 debug ospf event
8 debug ospf packet all
9
10 router ospf
11
12
13
14 network 10.10.23.0/24 area 0
15 network 10.10.35.0/24 area 0
```

Let's have a closer look at the commands in the file above (you are already familiar with some of them):

- `log file`: Same as with `zebra`, it specifies the file to which the OSPF related information is logged;
- `debug ospf event`: less detailed debugging, *i.e.*, only the coarse events, such as sending and receiving OSPF updates, can be seen;
- `debug ospf packet all`: more detailed debugging, *i.e.*, allows you to see the content of the sent and received OSPF updates;
- `router ospf`: enables the `ospfd` process;
- `network`: assigns an area to a particular network segment.

Using the example configuration file shown above and the address scheme of Figure 2, **create the `ospfd` configuration files for the routers `r1` and `r2` and place them in the same folder: `/home/lca2/Desktop/lab4/configs/`.**

In this section, you must have `zebra` running on all routers and `ospfd` running on all routers **except `r4`**. In order to start the `ospfd` process at router `r1` type the following command at `r1`'s terminal:

```
ospfd -d -f /home/lca2/Desktop/lab4/configs/ospfd_r1.cfg -i  
/home/lca2/Desktop/lab4/run/ospfd_r1.pid  
-z /home/lca2/Desktop/lab4/run/frr_r1.api -u root
```

Again, make sure that all processes are running by checking the list of running processes.

**Note:** OSPF takes some time to finish configuring all routers. Make sure you wait for some time (up to a minute) every time you run `ospfd`.

### Q3/ Answer to Lab 4 Part 1 Questions 3 and 4 on Moodle

**Solution:** *The packets are exchanged by multicast. If you happen to start the packet capture early, you might also encounter the LS update messages, some of which are exchanged with unicast. Therefore, there are two possible answers. The line corresponding to multicast looks like the following:*

```
<timestamp>: Hello sent to [224.0.0.5] via [r2-eth1:10.10.12.2].
```

### Q4/ Answer to Lab 4 Part 1 Question 5 on Moodle

**Solution:** *r1 is uniquely identified through its OSPF Router-ID: 10.10.12.1 or 10.10.11.1 or 10.10.14.1 using the hello protocol. (This answer could be different for different students, but it has to be one of the IP addresses of r1.)*

## 4.2.1 MONITORING COMMANDS

We have seen before that we can use command `ip route show` to display the IPv4 routing table. Now, we will see how this information is stored and managed by OSPF. OSPF stores all information about the networks it knows about in the OSPF database. An OSPF router also maintains a list of neighbours from whom, it expects periodic updates called link state advertisements (LSAs).

We will start by inspecting the neighbors of `r3`. For this, you can enter the monitoring mode of the `ospfd` daemon. This is done in the same way as for the `zebra` process (*i.e.*, `telnet localhost ospfd`). The password is `ospfd`. After that, you can display the content of the OSPF database using the command:

```
show ip ospf neighbor
```

**Q5/ Answer to Lab 4 Part 2 Questions 1 and 2 on Moodle**

**Solution:** *Two neighbours.*

*10.10.23.2*

*10.10.45.5*

*The answer to question 2 varies among the students.*

**Q6/ Answer to Lab4 Part 2 Questions 3 and 4 on Moodle**

**Solution:** *Dead time is the time after which the neighbour is considered dead and all its LSAs are removed from the database. Hello timer is the time after which it expects a hello message.*

*The Dead timer is 4 times the Hello timer, their values are 40 s and 10 s respectively.*

Next, we will look at the LSAs in the database of routers. For this, you can use the following set of commands.

```
show ip ospf database
show ip ospf database network
show ip ospf database router
show ip ospf database self-originate
```

**Q7/ Answer to Lab4 Part 2 Questions 5 to 8 on Moodle**

**Solution:**

*Question 5: The Link state ID of a router-LSA is the ID of the advertising router.*

*The Link ID of a transit network is the IP address of the Designated Router interface connected to this Ethernet LAN.*

*The Link ID of a stub network is the subnet address of this network.*

*Look at the network-LSAs at r3. The Link State ID of a network-LSA is the IP address of the Designated Router interface connected to this Ethernet LAN.*

*Question 6: There are two Link IDs in r3's router-LSA. The IDs depend on which is the DR of each of the two links.*

*Question 7: This answer depends on Q5. r3 advertises the network LSAs for which it is a DR, so it is possible that no network LSA is advertised by r3. Another possible answer is: 10.10.23.3 and 10.10.35.3.*

*Question 8: The correct answers among those listed are :*

*DR : r2 ; BDR r5 ; LSAs : 10.10.35.3*

*DR : None ; BDR r2 r5 ; LSAs : 10.10.23.3 and 10.10.35.3*

*DR : r5 ; BDR r2 ; LSAs : 10.10.23.3*

**Q8/ Answer to Lab4 Part 2 Question 9 on Moodle**

**Solution:** To find this out, first check the type of the self-originating LSAs at r1. It will be a router LSA. Then look at the router LSA database of r1. You will find three networks: 10.10.11.0, 10.10.12.1, and 10.10.14.0. One is a transit and the other two are stub. It's because r4 is not yet an OSPF router as we have not yet run the ospfd daemon on it.

**Q9/ Answer to Lab4 Part 2 Question 10 on Moodle**

**Solution:** There are 4 router LSAs and 4 network LSAs. Each router advertises 1 LSA. As there are 4 OSPF routers, we have 4 router LSAs. Each transit network has one LSA that is advertised by the designated router of the LSA. As there are 4 transit networks, there are 4 network LSAs.

John wants to see how far they are from their friends Jorah (h2) and Tyrion (h3) currently travelling through Valyria, accessible from network 10.10.35.0/24. From router r1, use the `show ip ospf route` command.

**Q10/ Answer to Lab4 Part 2 Questions 11 and 12 on Moodle**

**Solution:** The cost from r1 to the Valyrian network is 30, it goes through r2 and then either r3 or r5.

Note that h2 and h3 are both on the Valyrian network and that h1 is on network 10.10.11.0/24, thus packets between h1 and hosts from the Valyrian network should behave in a similar fashion.

**Q11/ Answer to Lab4 Part 2 Questions 13 and 14 on Moodle**

**Solution:** All traceroutes should not show the same path, some routes should go through r3 while others should go through r5. If we run traceroute multiple times, we expect that the percentage will be 50%-50%. This is because of Equal Cost Multipath (ECMP) behavior in Linux machines. A (uniform) hash function is applied on the { ip source, ip destination } tuple to select the next hop. Hence each tuple is randomly attributed to a next hop to ensure some **load balancing** of the two equal cost paths. See <https://codecave.cc/multipath-routing-in-linux-part-2.html>

### 4.3 CONFIGURING OSPF6D

OSPF for IPv6 was defined in the RFC 2740 and is known as OSPFv3. It is an IPv6 reincarnation of the OSPF protocol.

As multiple routing protocols can run in parallel on the majority of routers, FRR allows you to configure OSPFv3 in parallel to OSPFv2. Just like zebra and ospfd processes, the ospf6d process can be configured by editing a configuration file or via telnet.

Similar to ospfd, we provide the ospf6d configuration files for the routers r3, r4 and r5. The configuration file of ospf6d is a bit different from that of ospf. Below, we explain the file ospf6d.conf on r3.

### Script 3: Example of an ospf6d.conf file

```
1 hostname r3
2 password ospf6d
3 enable password ospf6d
4
5 log file /home/lca2/Desktop/lab4/logs/ospf6d_r3.log
6 debug ospf6 neighbor
7 debug ospf6 interface
8
9 interface r3-eth1
10 ipv6 ospf6 instance-id 1
11
12 interface r3-eth2
13 ipv6 ospf6 instance-id 1
14
15 router ospf6
16
17 interface r3-eth1 area 0.0.0.0
18   area 0.0.0.0 range 2001:1:0:23::/64
19
20 interface r3-eth2 area 0.0.0.0
21   area 0.0.0.0 range 2001:1:0:35::/64
```

To configure `ospf6d`, you need to first specify the interfaces on which you wish to enable OSPFv3. Then, you need to configure the OSPF area and network those interfaces belong to. The commands are.

- `interface <interface-name>`: Enable OSPFv3 on this interface.
- `interface <interface-name> area <A.B.C.D>`: Assigns the interface to a given area. Notice that although it is an IPv6 service, it uses a 32-bit area code that is represented in the dotted decimal format.
- `area <A.B.C.D> range <IPv6 network with mask>`: Specifies which networks belong to a given area.

**The configuration scripts of `r1` and `r2` are left for you to create.** You should place them in the same folder as earlier `/home/lca2/Desktop/lab4/configs/`.

In this section, you must have `zebra` running on all routers, and `ospfd` and `ospf6d` running on all routers **except `r4`**. In order to launch `ospf6d` on `r1`, you can type the following command at the terminal of the router:

```
ospf6d -d -f /home/lca2/Desktop/lab4/configs/ospf6d_r1.cfg -i
/home/lca2/Desktop/lab4/run/ospf6d_r1.pid
-z /home/lca2/Desktop/lab4/run/frr_r1.api -u root
```

Again, make sure that all processes are running by checking the list of running processes.

#### 4.3.1 MONITORING COMMANDS

To inspect the `ospf6d` database, you should execute the command: `telnet ::1 ospf6d`. The password is `ospf6d`. To display the content of the OSPF routing table:

```
show ipv6 ospf6 route
show ipv6 ospf6 route detail
```

Now, explore by yourself the available monitoring commands. Recall that you can press ? at any time to list the possible commands at an instant.

#### Q12/ Answer to Lab4 Part 2 Question 15 on Moodle

**Solution:** The command to check the spf tree is `show ipv6 ospf6 spf tree` or `show ipv6 ospf spf tree` and we observe that the cost introduced by each additional router is 10.

## 5 OSPF PLAYGROUND

In this section you will be confronted with a number of situations that might arise in an OSPF network. Answering the questions will allow you to better understand `ospfd` and `ospf6d`, and dynamic routing in general. You can use two terminals, one for the FRR process commands and one for the Linux commands. To have a second `xterm` window for `r1`, you can type: `xterm r1` in the `mininet>` prompt.

### 5.1 UNDERSTANDING NEIGHBORS IN OSPF

In this section, we will learn about how neighbors interact within OSPFv2 (`ospfd`).

Now, restart the Mininet network using the `python lab4_network.py` command. Don't forget to clear the mininet cache before restarting the network. If you did not enable the automatic start of zebra at all routers, manually do so at all routers. Activate `ospfd` at all routers **except r4**.

The next couple of questions will require the comparison of the OSPF database on `r5` before and after launching the `ospfd` process on `r4`. Take a snapshot of the database for your reference. Specifically, show `ip ospf database`, `show ip ospf database router`, and `show ip ospf database network`. Now, we will see how OSPF routers are synchronised. Launch the `ospfd` and `ospf6d` processes on `r4`. This will make `r4` an OSPF router. Wait for a minute and answer the following questions.

#### Q13/ Answer to Lab4 Part 3.1 Questions 1 and 2 on Moodle

**Solution:** Yes, with state Full.

In total, there are 8 states: DOWN, ATTEMPT, INIT, 2-WAY, EX-START, EXCHANGE, LOADING and FULL. <https://cyruslab.net/2012/04/01/ospf-finite-state-machine/>

#### Q14/ Answer to Lab4 Part 3.1 Question 3 on Moodle

**Solution:** We see three new router LSAs from `r1`, `r4`, and `r5`. `r1` and `r5` advertise a change in their connected networks, i.e., the change in networks `10.10.14.0` and `10.10.45.0` from stub networks to transit networks. `r4` on the other hand is just announcing its presence for the first time.

As there are two new transit networks, we also see two network LSA for networks `10.10.14.0` and `10.10.45.0`.

### 5.2 MODIFIED LINK METRIC

OSPF works by constructing a shortest path tree. By default, in OSPFv3, the directly connected subnets are treated as having the distance equal to 10. Each additional “hop” (router) adds 10 to this distance metric.

Nevertheless, `ospf6d` offer you the possibility to modify the metric of an arbitrary link, changing the desirability of the routes that contain this link.

Cersei (at King's Landing in `r1`), being the paranoid queen, wants to know if Dany is talking to Jorah behind her back. So, she orders that the (one way) IPv6 traffic from `h4` to `h2` to go via `r1` instead of the direct route. To fulfill this task, you need to modify the cost of the link between `r2` and `r5` so that the total cost of routing through `r2` → `r1` → `r4` → `r5` is less than the direct route. The cost of an interface is set in the interface setup. The syntax for specifying cost is

```
ipv6 ospf6 cost x
```

#### Q15/ Answer to Lab4 Part 3.1 Question 4 on Moodle

**Solution:** *The minimum number of required cost updates is 2. We need to change costs on `r2 – eth2` and `r2 – eth3` to > 40.*

### 5.3 BROKEN LINK

John's dragon Drogon sometimes gets restless and burns things down. In one such incident, he burnt down the link between `SW2` and `r1`. To simulate the broken link between `r1` and `r2`, shutdown the `r1-eth1` interface on `r1`. Make sure you take a snapshot of the OSPF databases of router `r2` before doing so, just as you did in the Section 5.1. To shutdown the link, type on `r1` the following commands:

```
telnet localhost zebra
enable
configure terminal
interface r1-eth1
shutdown
```

Note that it is convenient to use the “on the fly configuration” here. Wait for a minute and then answer the following question.

#### Q16/ Answer to Lab4 Part 3.2 Question 1 on Moodle

**Solution:** *After the expiration of the Dead timer of 40s, the network LSA from 10.10.12.0 is marked invalid by setting its age to maxAge of 3600 because this network is no longer a transit network [next two options NA]. Router LSA for router `r1` was updated. In this router LSA, a link entry was removed; reason: change in the connected links. Router LSA for router `r2` was updated. In this router LSA, a link entry was updated; reason: connected network becomes stub. Third line: all NA.*

The crash of an OSPF process also has a similar behaviour but on all interfaces instead of just one.

#### Q17/ Answer to Lab4 Part 3.2 Question 2 on Moodle

**Solution:** *No, we can't ping as the interface is down.*

### Q18/ Answer to Lab4 Part 3.2 Question 3 on Moodle

**Solution:** Yes, it pings. Indeed, r1 is not announcing anymore a route toward 10.10.12.0/24, but r2 continue announcing that it has route toward this network. Thus, thanks to OSPF, r1 – eth1 is reachable through r2.

### Q19/ Answer to Lab4 Part 3.2 Question 4 on Moodle

**Solution:** For OSPF, the network 10.10.12.0/24 is advertised through only r2. For OSPF, r1 and r2 are not neighbours and they do not communicate between each other. Consequently, 10.10.12.0/24 is a stub network and packets cannot transit through it. Packets going from r3 to h1 transit through r5 and not r2. For packets that go from h1 to r2 – eth1, they are delivered from r1 to r2, as r2 – eth1 is considered as part of the 10.10.12.0/24 LAN directly connected to r1, this is independent of OSPF. The other way around from r2 to h1 goes through r5.

r2 → r5 → r4 → r1 → h1

r3 → r5 → r4 → r1 → h1

## 6 BONUS: SOFTWARE DEFINED NETWORKING

For students who could not run openVSwitch switches in the previous labs (and were using LinuxBridges), please contact the TAs to borrow a Minix for this part.

Software defined networking (SDN) is an approach to TCP/IP networking that allows network administrators to manage services through flexible interfaces provided by a control-layer. A typical SDN network consists of routers or switches interconnected, each of them with a “listener” daemon running in which they receive forwarding-decision rules, called flows, from one (or many) controller(s) using, for example, the OpenFlow protocol. The network administrators make changes to the controller and these changes are disseminated through the control-layer (typically another IP-based connection) so that appropriate routing/switching decisions can be applied.

The Mininet virtual environment used in this lab is compatible with SDN. In fact, the openVSwitch (OVS), which is the switch we have been using so far in this lab, is a software listener switch that is controlled using the OpenFlow protocol. The central controller that comes with Mininet has no special features or policies, which make the openVSwitches used in the virtual environment, to behave as a basic L2-switch.

In order to explore SDN, we need a new controller. We will use the RYU controller <sup>1</sup>, which is an open-source controller written in Python. In the lab4/SDN folder, unzip the file ryu.zip where you will find the source files of RYU. If you followed the path consistency instructions, the command

```
cd /home/lca2/Desktop/lab4/SDN && unzip ryu.zip
```

should unzip the folder. Otherwise, make sure the uncompressed folder is located in the SDN folder and its name is ryu (case-sensitive). **If you are using Minix**, run the following command before proceeding further:

<sup>1</sup><https://github.com/faucetsdn/ryu>

```
pip3 install --ignore-installed PyYAML
```

Run the script `install_ryu.sh` as root on your virtual machine to install RYU. You can check if RYU is properly installed by trying out the command `ryu-manager -h`. It should print the help menu without any errors. If instead it prints the error message "cannot import name ALREADY\_HANDLED", then try downgrading the `eventlet` python package by typing on a terminal:

```
pip3 install eventlet==0.30.2
```

Please contact the TAs if you encounter another issue with the installation of `ryu`.

In Mininet, the configuration changes for using an external controller are minimum. Basically we need to call the `RemoteController` class by importing it from `mininet.node`, and then when we call the constructor `Mininet`, we pass the attribute `controller=RemoteController`. With this configuration, the switches will look on the VM's loopback address (default port 6633) for the controller.

The topology for this section is composed of 5 switches and is depicted in Figure 3. The script `lab4_sdn.py` (available on Moodle) has been created for you to match the topology described.

Figure 3: Lab 4 SDN topology

**Q20/ Answer to Lab4 Part 4 Question 1** on Moodle

**Solution:** There is only one single subnet, thus all IP addresses should share a common prefix. The largest possible netmask length is /21.

## 6.1 CONTROLLING THE OPENFLOW SWITCH IN STANDALONE MODE

The OVS switch comes with the `ovs-ofctl` utility, which uses the terminal prompt to send basic OpenFlow messages, for basic configuration and retrieving important information such as installed flows, port information, dump statistics, etc. To display a complete list of the commands (with a brief description of what it does), type the `ovs-ofctl -h` command from a terminal prompt. Note that Mininet also comes with a similar utility called `dpctl`, which has a short version of the `ovs-ofctl` utility. Unlike the latter, `dpctl` is available through the `mininet>` prompt.

Let's analyze the behavior of the OVS switch in the absence of the controller. Run the `lab4_sdn.py` script. Now, from `h4` try to make three pings to `h5`:

```
mininet>h4 ping -c 3 h5
```

The pings are unsuccessful as the switches in the network don't know what to do with the incoming packet. Now, let's use the `ovs-ofctl` utility to help `h4` and `h5` communicate. From a new terminal prompt (from Linux, not Mininet), type the following commands:

```
sudo ovs-ofctl add-flow SW4 in_port=1,actions=output:3
sudo ovs-ofctl add-flow SW5 in_port=3,actions=output:1
```

From the commands above:

- `add-flow`: refers to the command we are sending to the OVS switch, other options are *del-flow*, *dump-flows*, *dump-port*, *mod-port*, etc.
- `<switch>`: refers to the OVS switch we would like to send the message to. By default it resolves the names of the switches that are in the same machine, for others we need to specify IP address and TCP port.
- `in_port=1`: we tell the OVS switch on which port it should apply the flow to, in the inward direction.
- `actions=output:3`: we tell the OVS switch, what are we doing with packets matching the flow statement. In this case, we just send it out through a particular interface. Other options include flooding to all ports, setting a new *next-hop*, changing a particular field in the IP packet (priority, TTL, flags), etc.

### Q21/ Answer to Lab4 Part 4 Question 2 on Moodle

**Solution:** In `h5`, we see ARP request arriving from `h4` and we see that `h5` replies to these packets. In `h4` we do not see any ARP reply, only ARP requests. We can suspect there is traffic flowing in one direction thus we are missing flow configuration in the reverse path. By applying the following commands, the ping starts to succeed:

```
sudo ovs-ofctl add-flow SW4 in_port=3,actions=output:1
sudo ovs-ofctl add-flow SW5 in_port=1,actions=output:3
```

## 6.2 CONTROLLING THE OPENFLOW SWITCH USING RYU

Now it is time to use a remote controller. Before continuing, make sure you erase all flows from *SW4* and *SW5* by issuing the command `ovs-ofctl del-flows <switch>` from a Linux's terminal window (as root).

Stop the simulation in Mininet and start the RYU controller using a separate Linux's terminal window:

```
sudo ryu-manager ryu.app.simple_switch_13 ryu.app.ofctl_rest
```

The above command runs the RYU controller with the `simple_switch_13` applications. Leave it running on a separate terminal. Applications are “functionality add-ons” that are loaded onto the RYU controller, as the controller itself doesn't do much. In particular, the `simple_switch` application is the same as the one that comes as default component in Mininet's controller implementation, which makes the OpenFlow switches to act as a “type” of layer-2 learning switch. The application learns MAC addresses, and the flows it installs are exact-matches on as many fields as possible. Therefore, for different TCP/UDP connections between two hosts, you will have different flows being installed.

We have also specified the use of application `ofctl_rest`. This application is used by RYU to access the flow tables of the switches. This allows RYU to write to the switches and read from them. The RYU controller comes with a few other applications that are located in the

`/home/lca2/Desktop/lab4/SDN/ryu/ryu/app` folder.

For all cases, start the RYU controller first, and then start Mininet by running `lab4_sdn.py`. In this way, you can see the progress of all logs from the switches in the RYU controller console, which will be helpful to answer many questions in this section.

With the controller started, the OVS switches should now have automatic flows installed for every packet and all hosts should be reachable. From the `mininet>` prompt, do a `h4 ping -c 1 h5` command.

**Q22/ Answer to Lab4 Part 4 Question 3 on Moodle** *Solution:* The topology includes loops. In normal switches loops are handled by the Spanning-Tree Protocol (STP). As the `simple_switch_13` application does not implement any STP, the loop in the network makes packets to multiply exponentially, causing a congestion.

Use the `ovs-ofctl show <switch>` and `ovs-ofctl dump-flows <switch>` commands (from Linux's terminal) and notice the flows in the switches. Now, stop the RYU controller by using `Ctrl + C` in the Linux terminal window. Next, let's explore a different application.

Now, start the RYU controller using the following command:

```
sudo ryu-manager ryu.app.simple_switch_stp_13 ryu.app.ofctl_rest
```

Wait around one minute and keep looking at the output from the RYU controller. Do `pingall` from the Mininet prompt.

Does it work now? Use the `ovs-ofctl show <switch>` and `ovs-ofctl dump-flows <switch>` commands (from Linux's terminal) and try to discover how the `simple_switch_stp` component solves the previous problem.

**Q23/** Answer to **Lab4 Part 4 Question 4** on Moodle

**Solution:** The app implements the STP which uses the switch with lowest `dpid` as the root and from there builds a spanning tree. If we check the prescribed command for all switches, we will see shut-down interface(s) identified through `NO_FWD NO_PACKET_IN`.

**Q24/** Answer to **Lab4 Part 4 Question 5** on Moodle

**Solution:** STP computes the shortest paths to the root bridge. The possible spanning trees are:

Root: SW1 Disabled links: SW2-SW3 SW4-SW5

Root: SW2 Disabled links: SW1-SW3 SW4-SW5

Root: SW2 Disabled links: SW1-SW3 SW3-SW5

Root: SW3 Disabled links: SW1-SW2 SW2-SW4

Root: SW3 Disabled links: SW1-SW2 SW4-SW5

Root: SW4 Disabled links: SW1-SW3 SW2-SW3

Root: SW4 Disabled links: SW1-SW3 SW3-SW5

Root: SW5 Disabled links: SW1-SW2 SW2-SW3

Root: SW5 Disabled links: SW1-SW2 SW2-SW4
