

Minimizing Functions of Multiple Variables

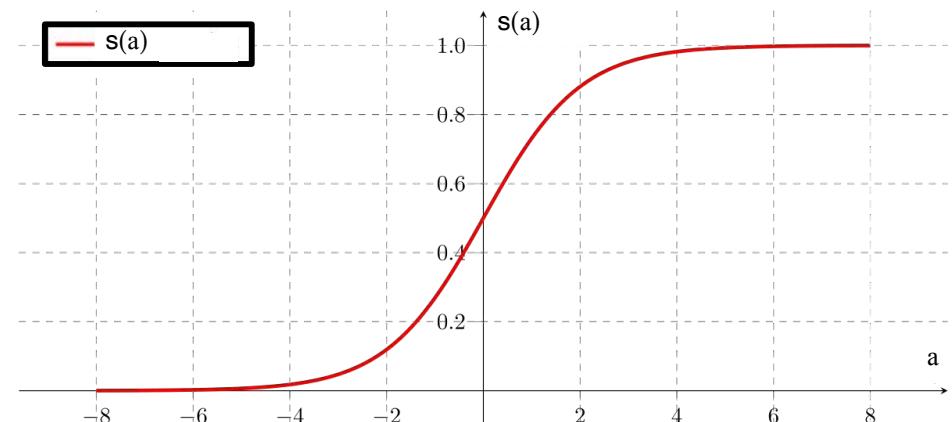

Pascal Fua
IC-CVLab

Reminder: Logistic Regression

$$y(\mathbf{x}; \tilde{\mathbf{w}}) = \sigma(\tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}})$$

$$= \frac{1}{1 + \exp(-\tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}})}$$

Given a **training** set $\{(\mathbf{x}_n, t_n)_{1 \leq n \leq N}\}$ minimize

$$E(\tilde{\mathbf{w}}) = - \sum_n (t_n \ln y(\mathbf{x}_n) + (1 - t_n) \ln(1 - y(\mathbf{x}_n)))$$

with respect to $\tilde{\mathbf{w}}$.

Reminder: Maximizing the Margin

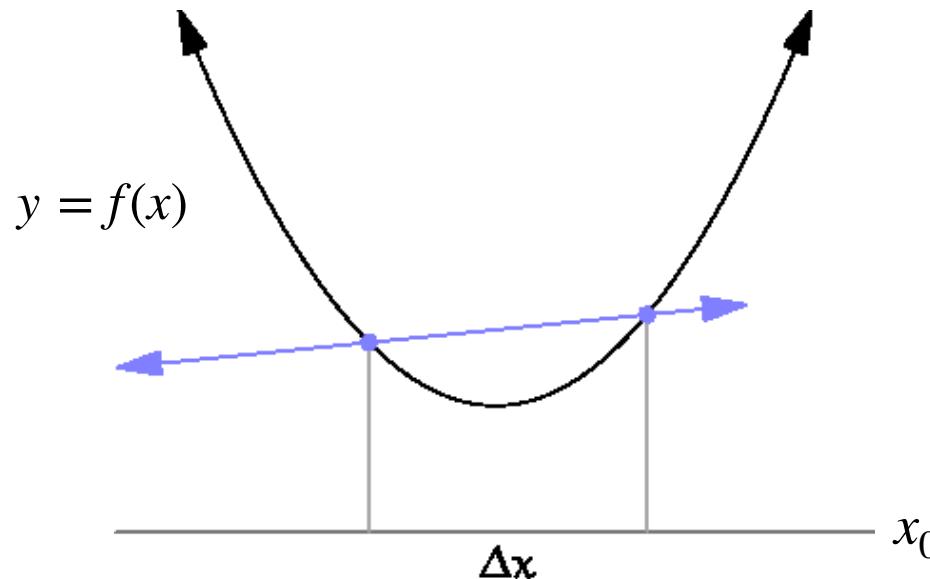

$$\mathbf{w}^* = \operatorname{argmin}_{(\mathbf{w}, \{\xi_n\})} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_{n=1}^N \xi_n,$$

subject to $\forall n, t_n \cdot (\tilde{\mathbf{w}} \cdot \mathbf{x}_n) \geq 1 - \xi_n$ and $\xi_n \geq 0$.

- C is constant that controls how costly constraint violations are.
 - The problem is still convex.
-
- How do you minimize a function of several variables?
 - Why do we prefer convex problems?
 - How do you impose constraints?

→ Let's talk about that today.

Derivative of a 1-Variable Function

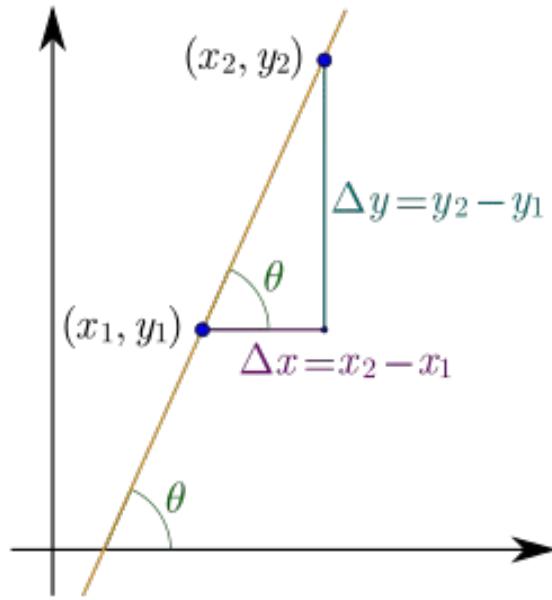

- The derivative of a function $y = f(x)$ of a single variable x is the rate at which y changes as x changes.
- It is measured for an infinitesimal change in x , starting from a point x_0 , and written as

$$f'(x_0) = \frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{f(x_0 + \Delta x) - f(x_0)}{\Delta x}$$

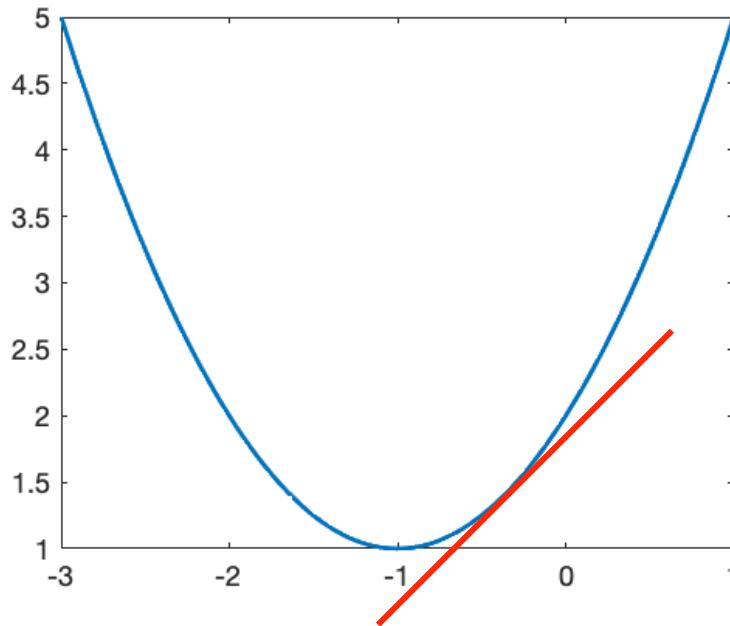

→ The derivative is the slope of the tangent at x_0 .

Derivative of a Linear Function

- The tangent to the function is the function itself: The slope is constant.
- For example, $y = 2x - 1$ and $\frac{dy}{dx} = 2$.

Derivative of a Non-Linear Function

- The tangent (in red) to the function varies with x and so does the slope.
- For example, $y = x^2 + 2x + 2$ and $\frac{dy}{dx} = 2x + 2$.

Evolution of the Tangent

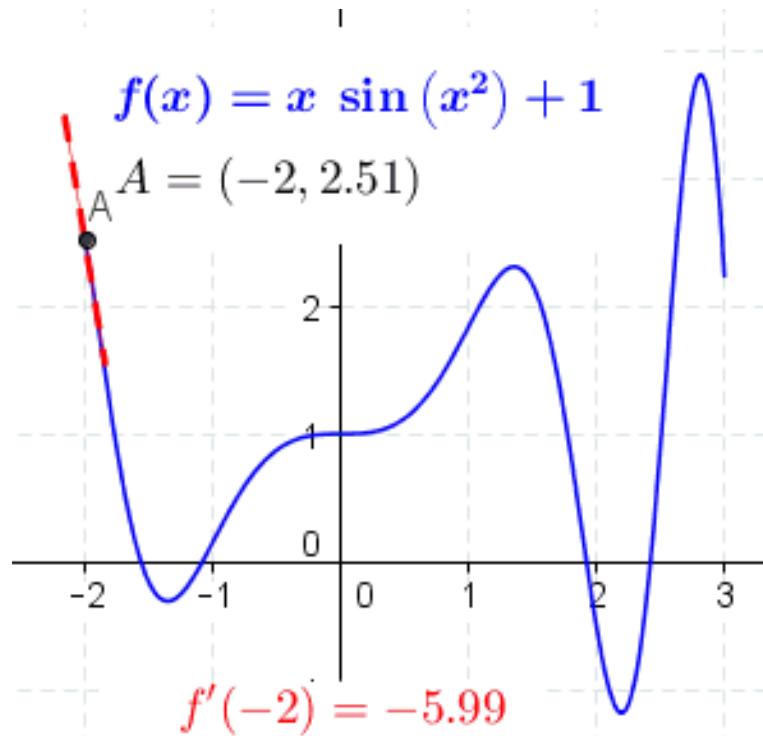

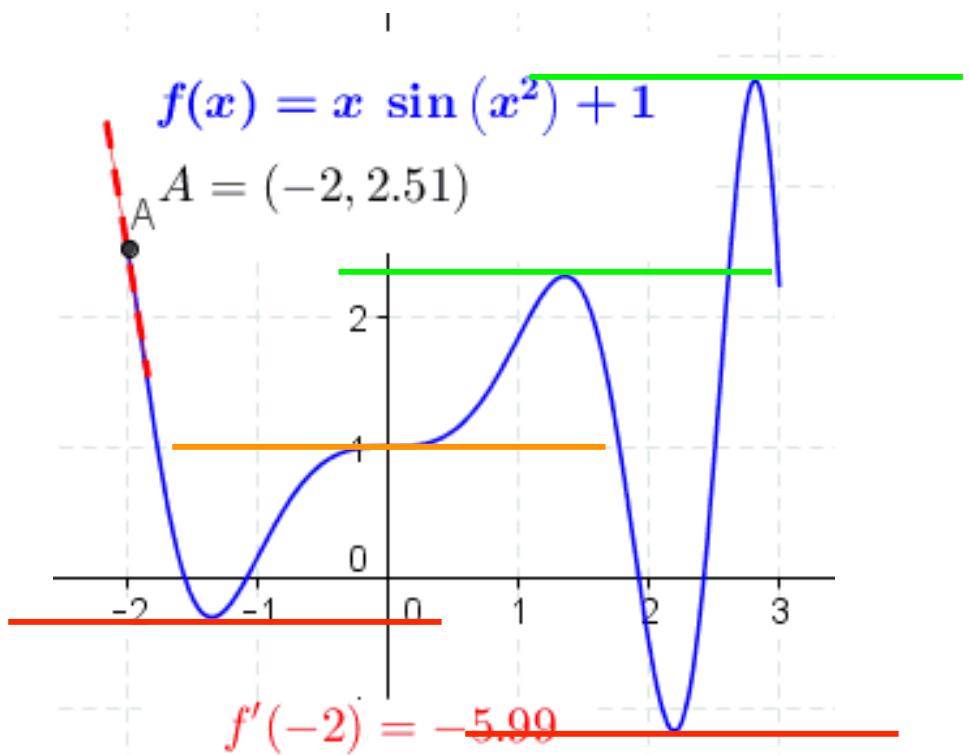

Figure from Wikipedia

$$y = x \sin(x^2) + 1$$

$$\frac{dy}{dx} = \sin(x^2) + 2x^2 \cos(x^2)$$

First and Second Derivatives

$$y = x \sin(x^2) + 1$$

$$\frac{dy}{dx} = \sin(x^2) + 2x^2 \cos(x^2)$$

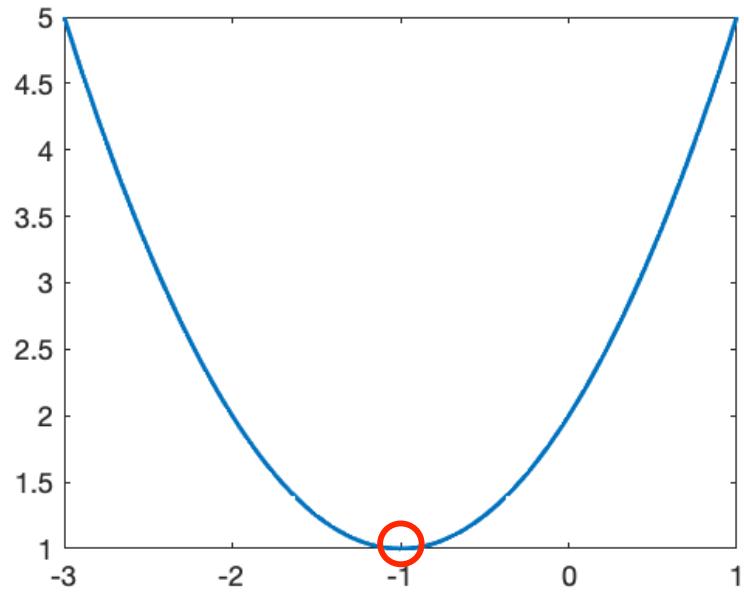

$$\frac{d^2y}{dx^2} = 6x \cos(x^2) - 4x^3 \sin(x^2)$$

$$\frac{dy}{dx} = 0 \text{ and } \frac{d^2y}{dx^2} > 0 : \text{Minimum}$$

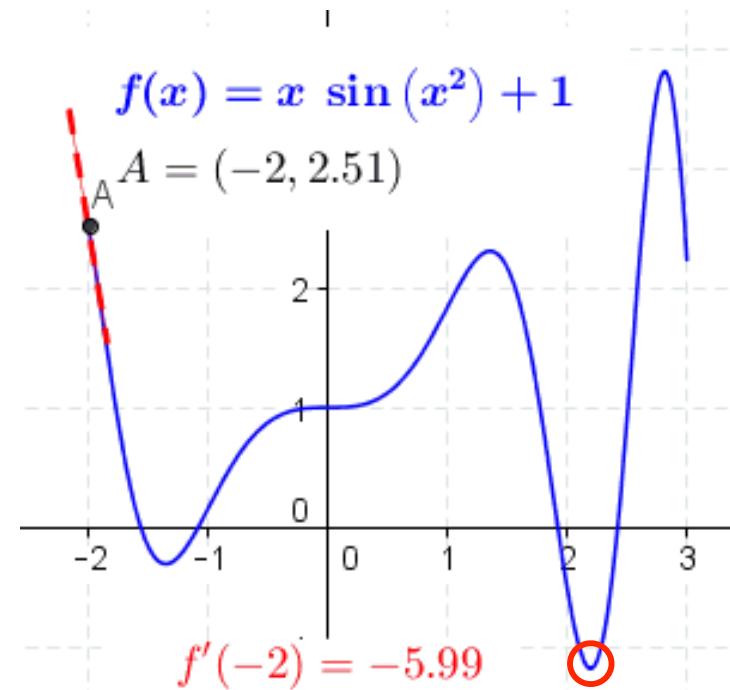

$$\frac{dy}{dx} = 0 \text{ and } \frac{d^2y}{dx^2} < 0 : \text{Maximum}$$

$$\frac{dy}{dx} = 0 \text{ and } \frac{d^2y}{dx^2} = 0 : \text{Saddle}$$

Convex vs Non-Convex

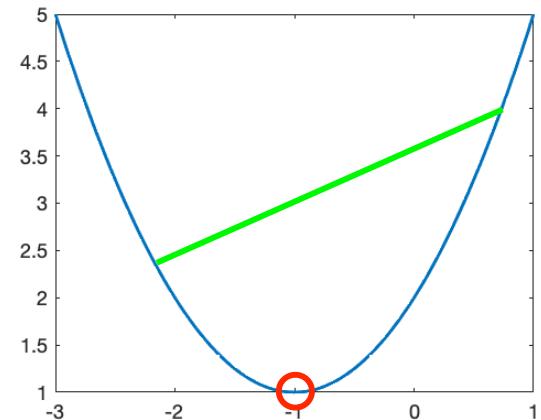

- There is only one minimum.
- The second derivative is ≥ 0 .

- There are several **local** minima.
- There is one global minimum.

→ Non-convex functions are much more difficult to minimize than convex ones.

Minimizing a Convex Function

The line segment between any two points on the curve lies above the curve.

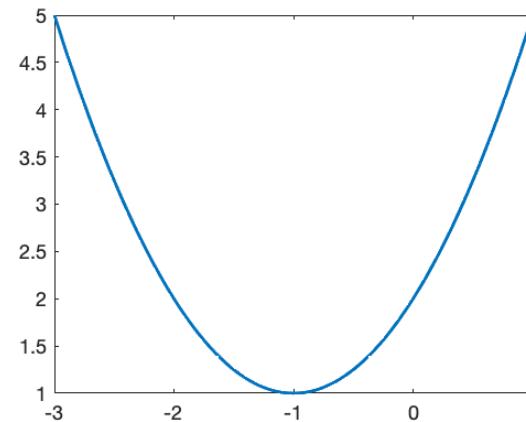

$$\frac{df(x^*)}{dx} = 0$$

For some simple functions this can be done in closed form, that is, by solving an equation.

Minimizing a Simple Convex Function

$$f(x) = x^2 + 2x + 2$$

$$\frac{df(x)}{dx} = 2x + 2$$

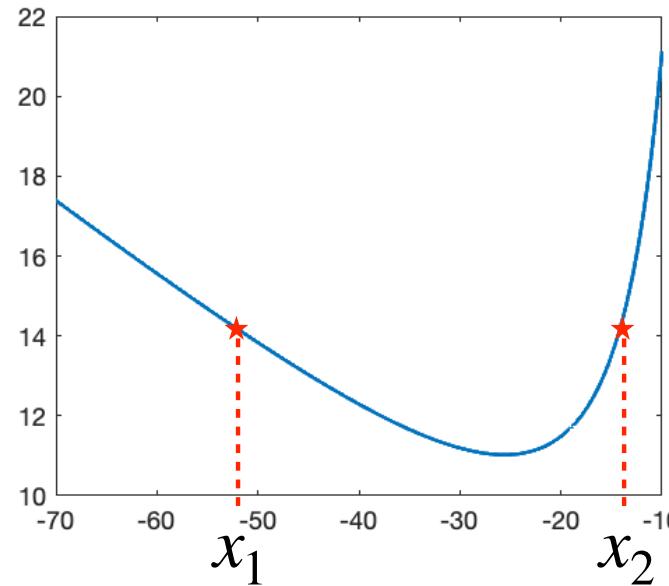

$$\begin{aligned}\frac{df(x^*)}{dx} = 0 &\Leftrightarrow 2x^* + 2 = 0 \\ &\Leftrightarrow 2x^* = -2 \\ &\Leftrightarrow x^* = -1\end{aligned}$$

Minimizing a Generic Convex Function

When the minimum cannot be found in closed-form, we use the derivative:

At x_1 , the slope is negative.
Hence, one should move in
the positive direction
($\Delta x > 0$) to go towards the
minimum

At x_2 , the slope is positive.
Hence, one should move in
the negative direction
($\Delta x < 0$) to go towards the
minimum

→ One should move in the direction opposite to the derivative
for minimization

Minimizing a Convex Function

Simplest algorithm:

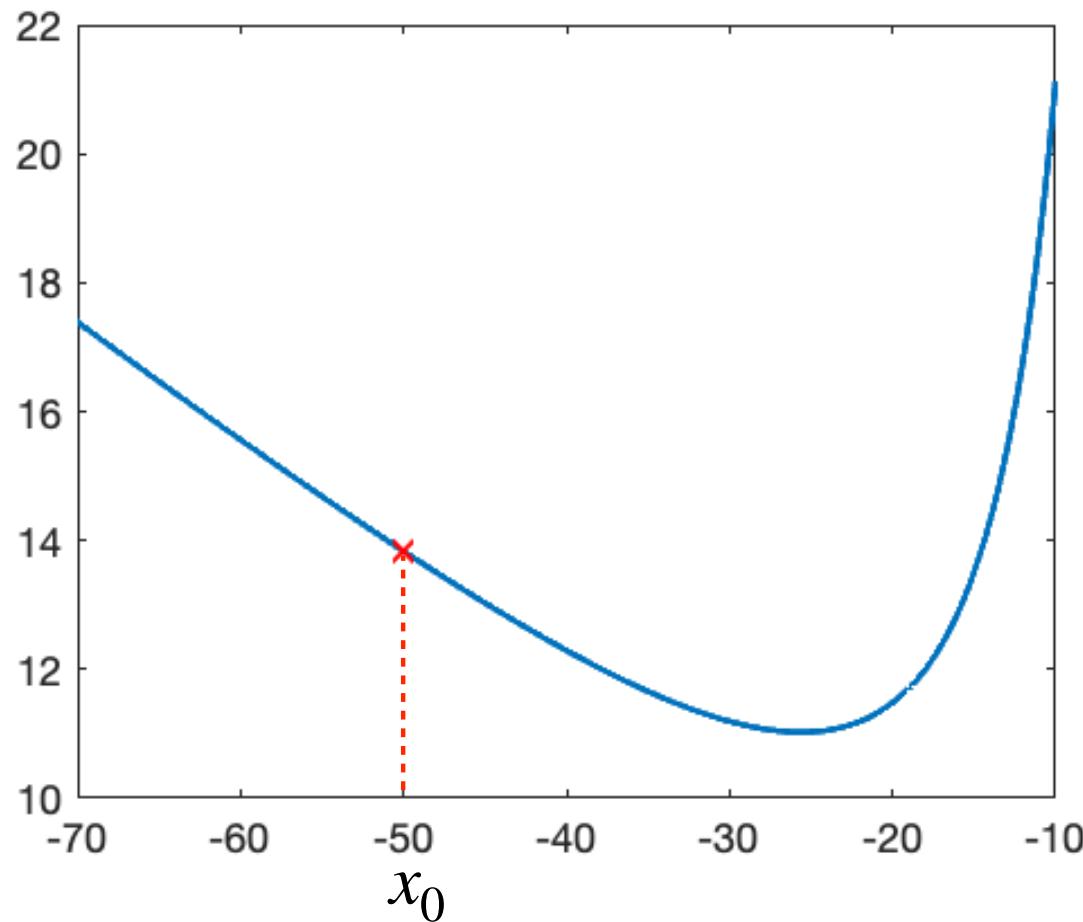

1. Initialize x_0 (e.g., randomly)

2. While not converged

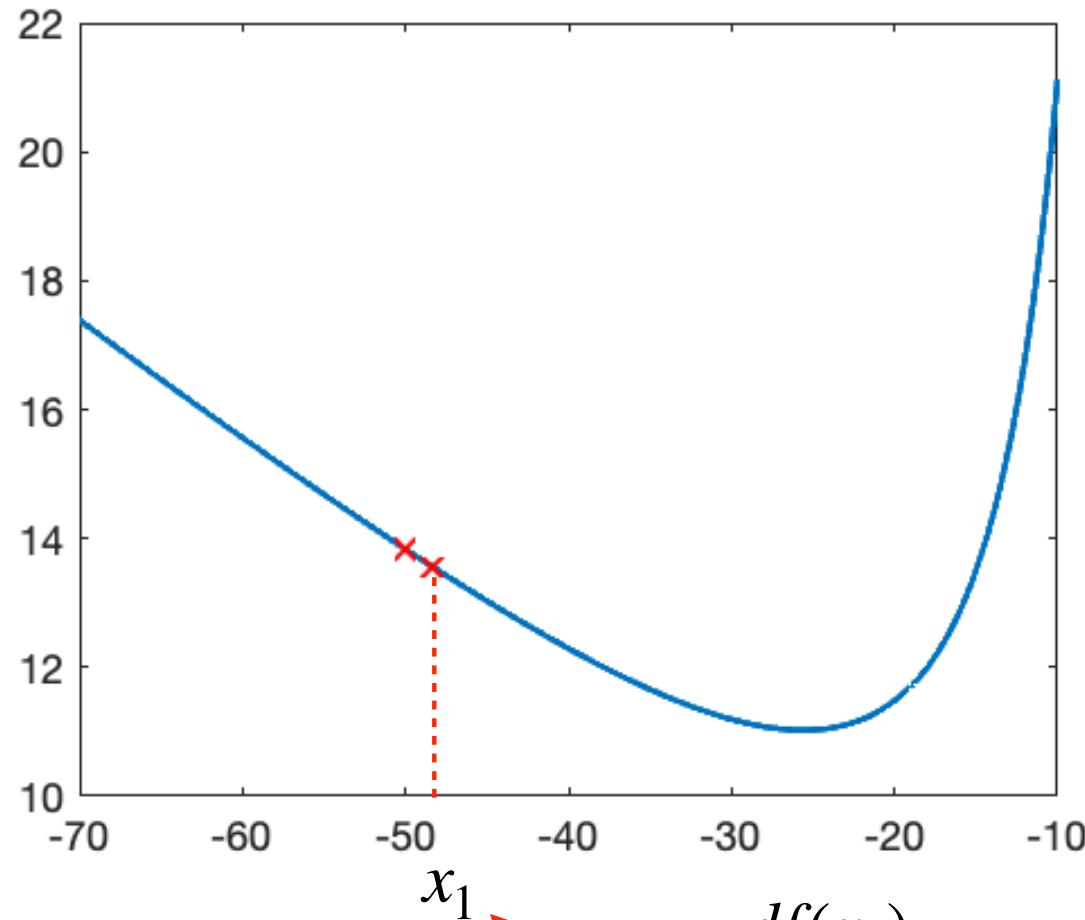

- 2.1. Update $x_k \leftarrow x_{k-1} - \eta \frac{df(x_{k-1})}{dx}$

- η defines the step size of each iteration.
- In ML, it is often referred to as the *learning rate*.

Minimizing a Convex Function

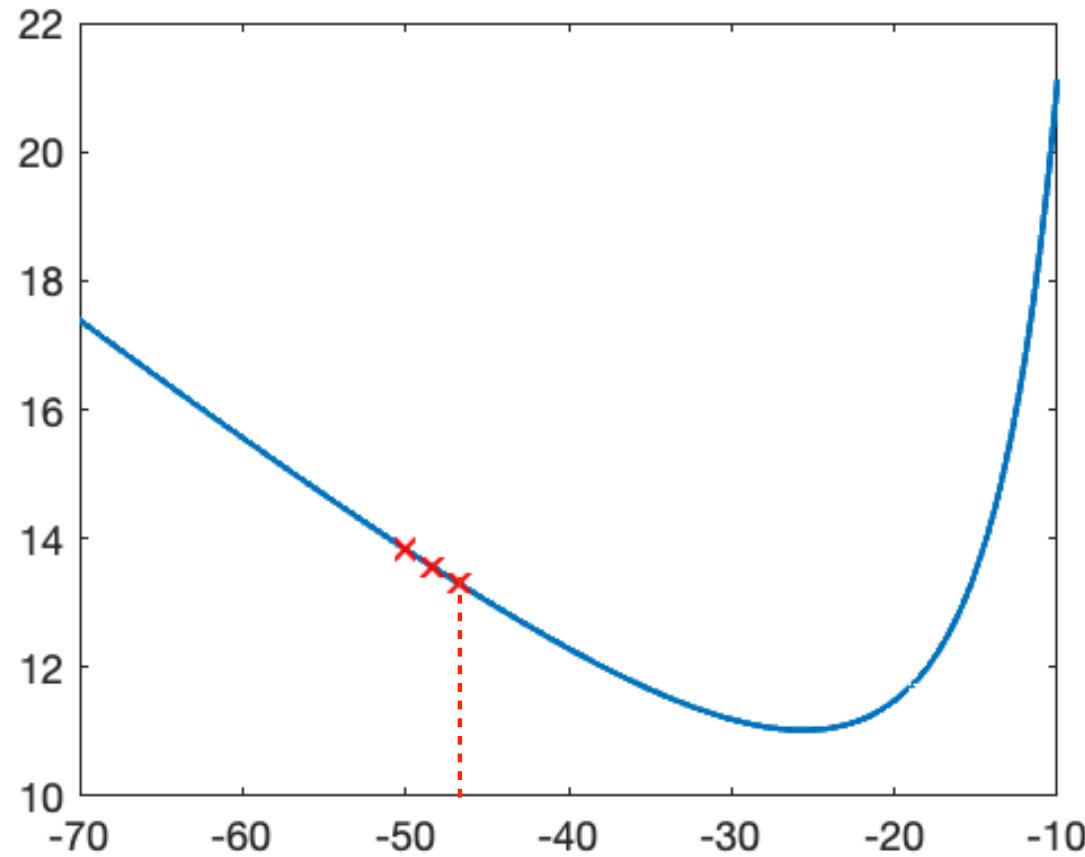

Minimizing a Convex Function

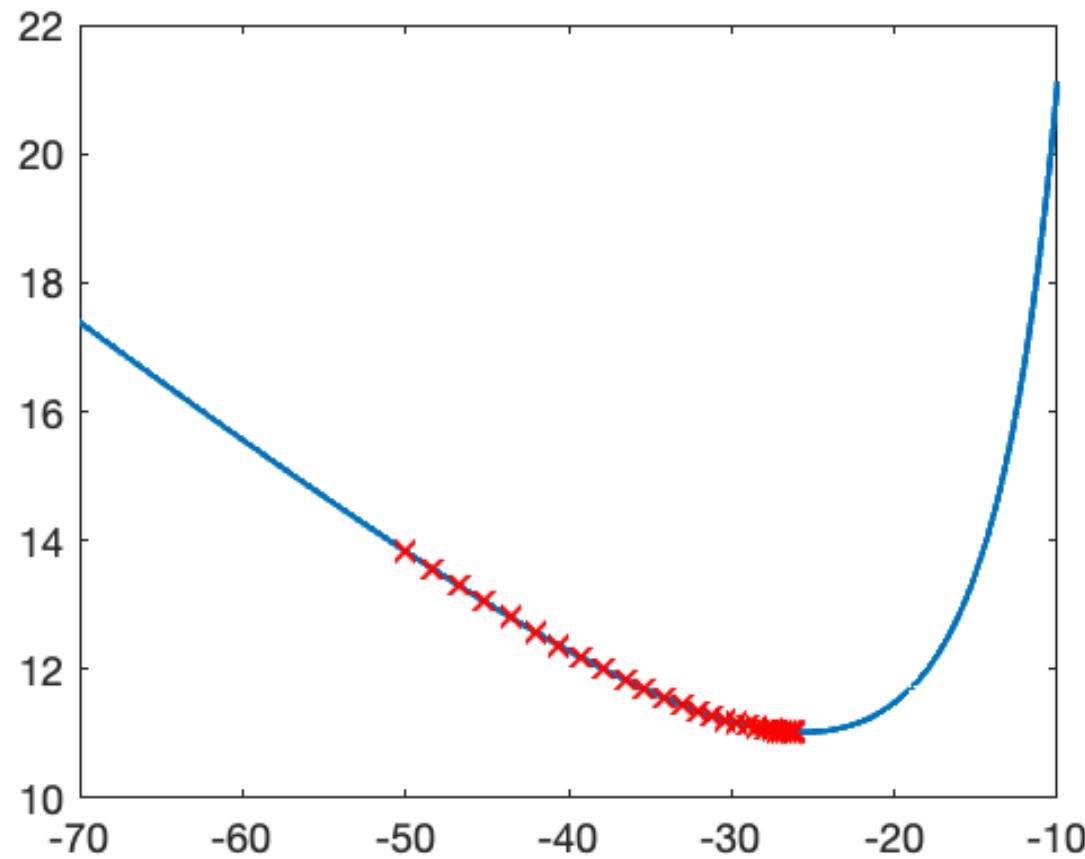

$$x_0 - \eta \frac{df(x_0)}{dx}$$

Minimizing a Convex Function

$$x_2 = x_1 - \eta \frac{df(x_1)}{dx}$$

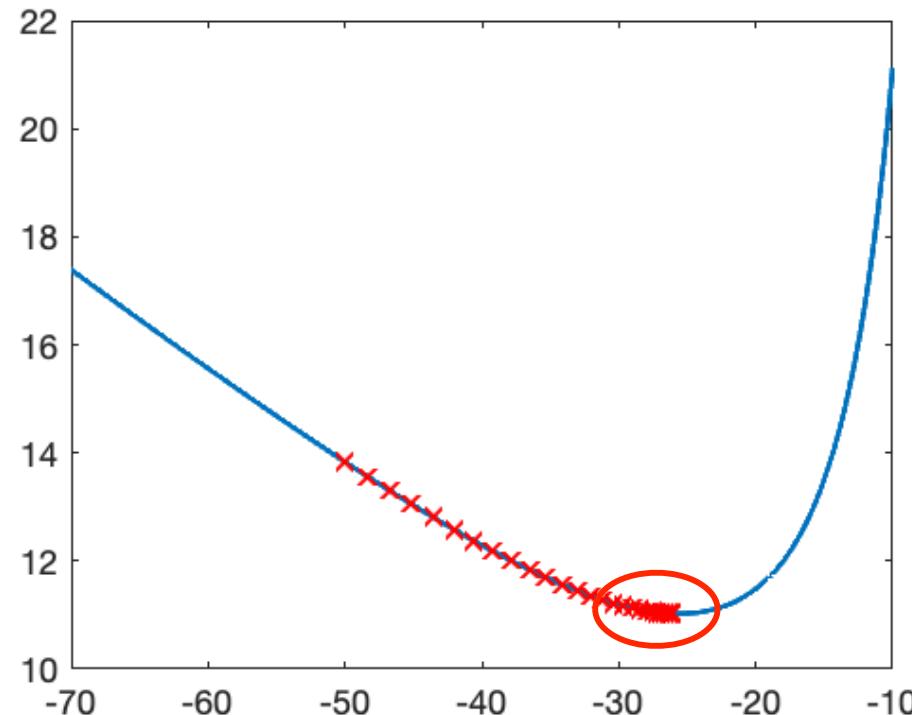

Minimizing a Convex Function

Minimizing a Convex Function

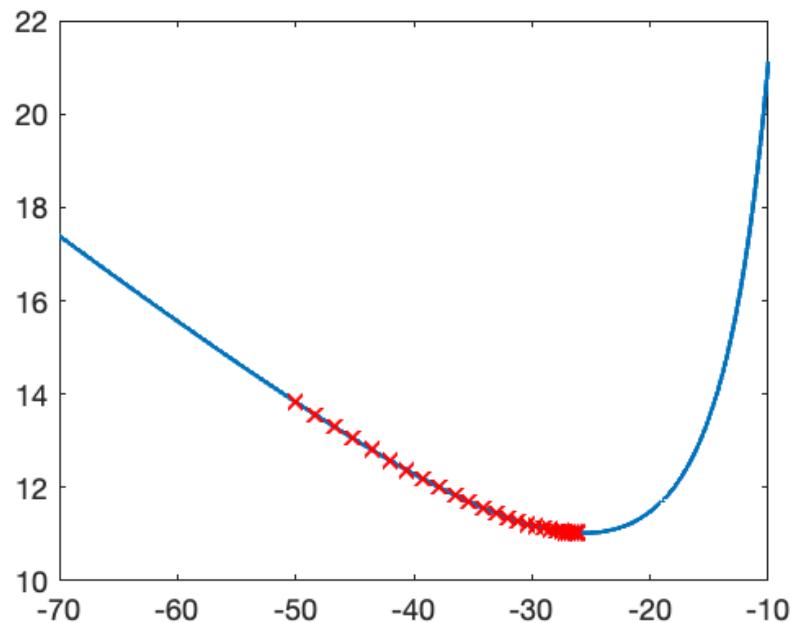

Potential stopping Criteria:

- Change in function value less than threshold: $|f(x_{i-1}) - f(x_i)| < \delta$.
- Change in parameter value less than threshold: $|x_{i-1} - x_i| < \delta$.
- Maximum number of iterations reached without a guarantee to have reached the minimum.

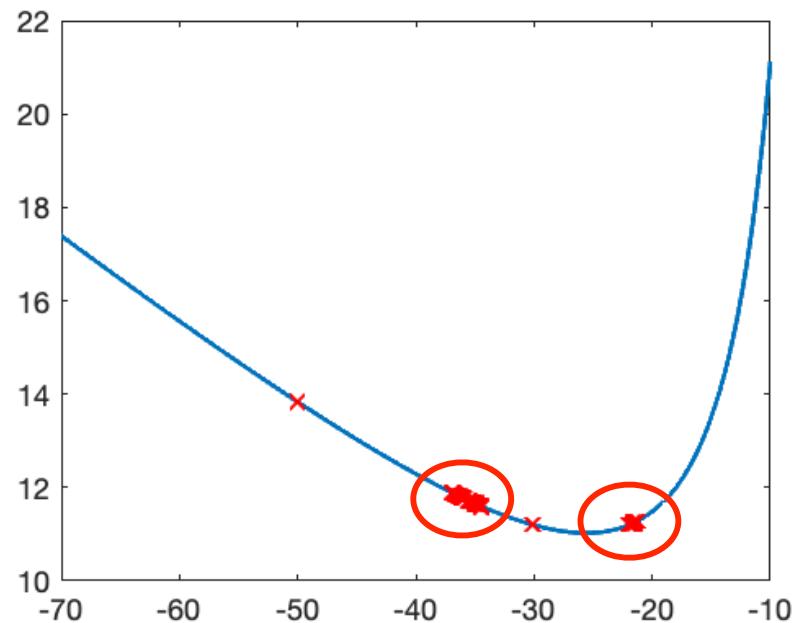

Influence of the Step Size

$$\eta = 10$$

The steps are of the appropriate size for convergence.

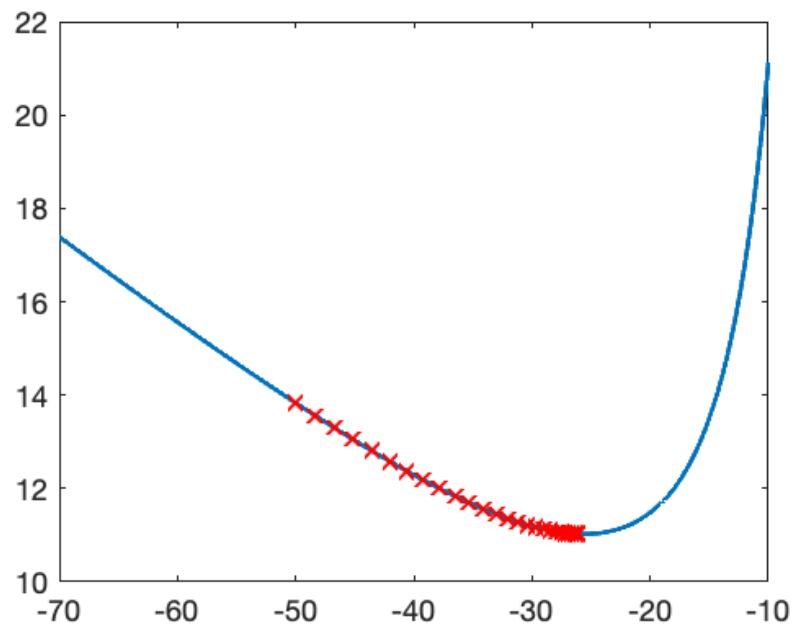

$$\eta = 120$$

The steps are too large and the algorithm starts jumping between these two points.

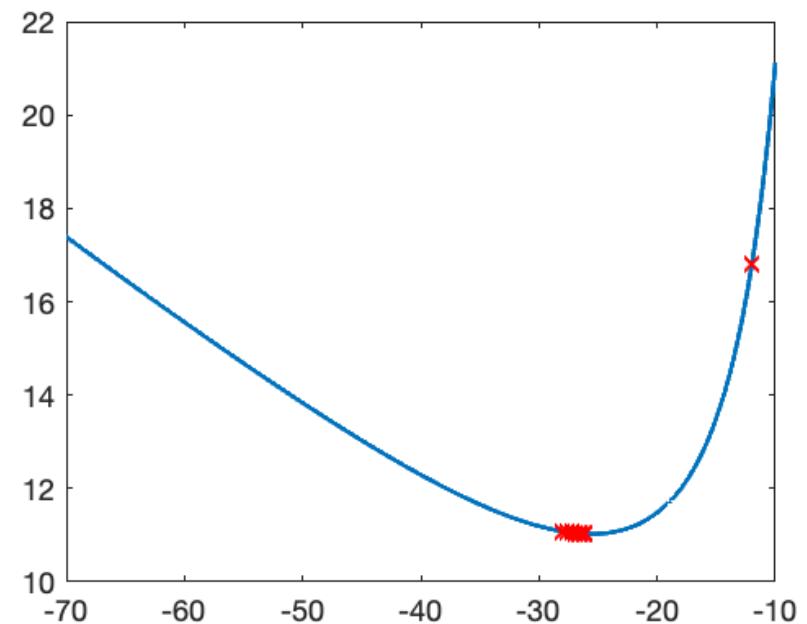

Influence of the Starting Point

$$x_0 = -50$$

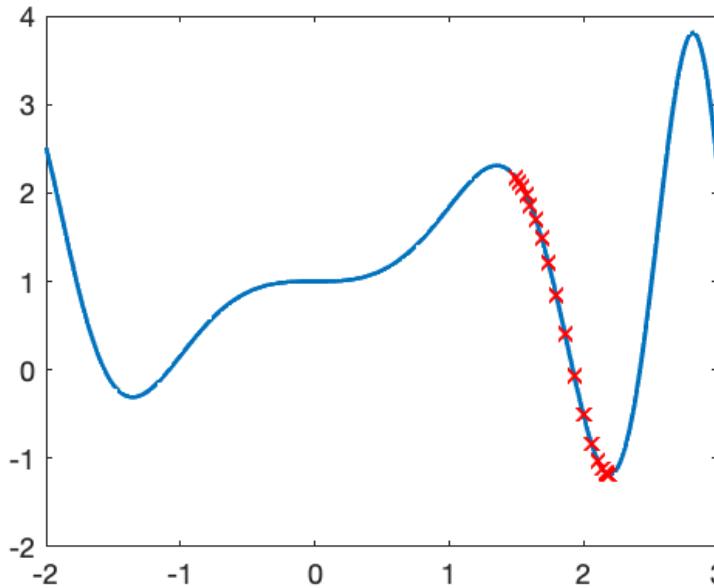

Converges.

$$x_0 = -12$$

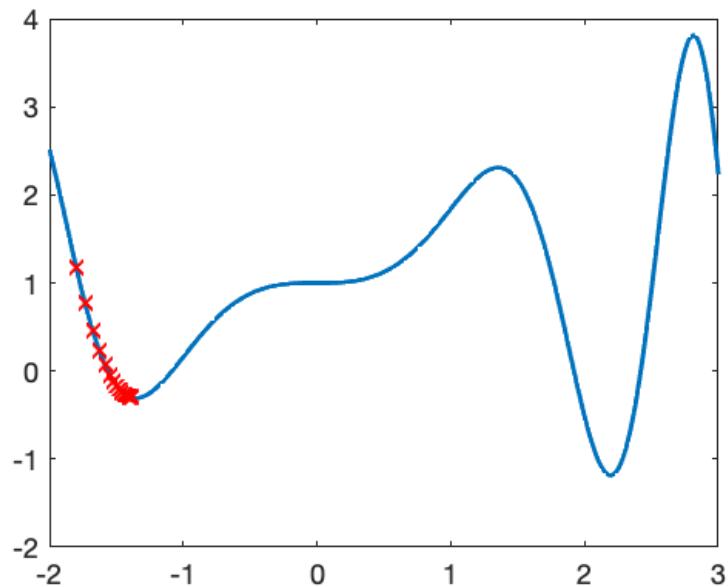

Converges to the same place,
but faster.

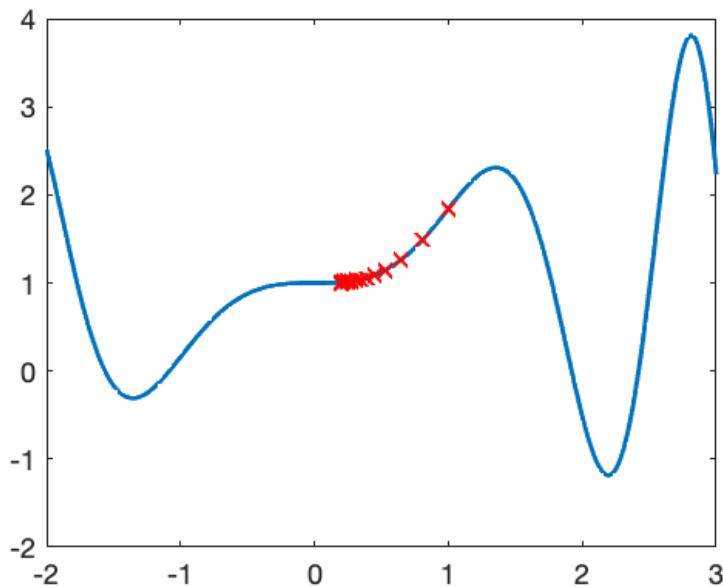

Minimizing a Non-Convex Function

$x_0 = 1.5$
Global minimum

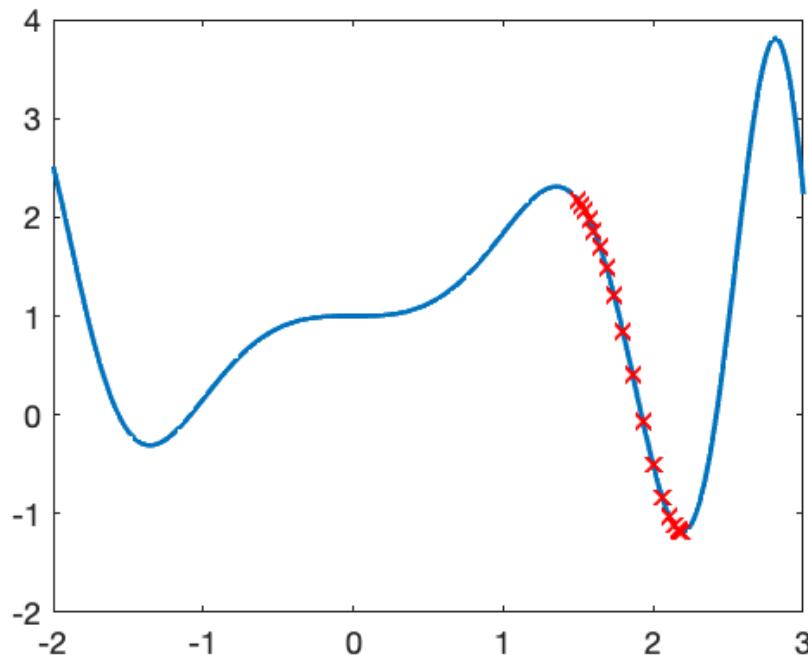

$x_0 = -1.8$
Local minimum

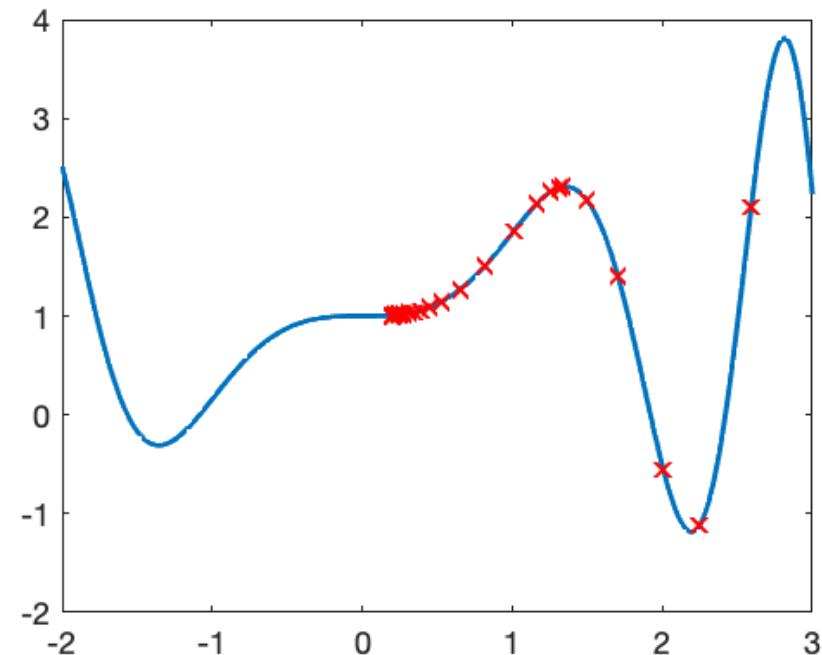

$x_0 = 1$
Saddle point

Minimizing a Non-Convex Function

$\eta = 0.01, x_0 = 1.5$
Global minimum

$\eta = 0.1, x_0 = 1.5$
Saddle point

→ No guarantees when the function is not convex!

Functions of Multiple Variables

Multivariate function:

$$f : R^D \rightarrow R$$

$$y = f(\mathbf{x}) = f(x_1, \dots, x_D)$$

Partial derivative:

$$\frac{\delta y}{\delta x_d} = \lim_{\Delta x \rightarrow 0} \frac{f(\dots, x_d + \Delta x, \dots) - f(\dots, x_d, \dots)}{\Delta x}$$

Gradient vector:

$$\nabla f = \left[\frac{\delta f}{\delta x_1}, \dots, \frac{\delta f}{\delta x_D} \right]$$

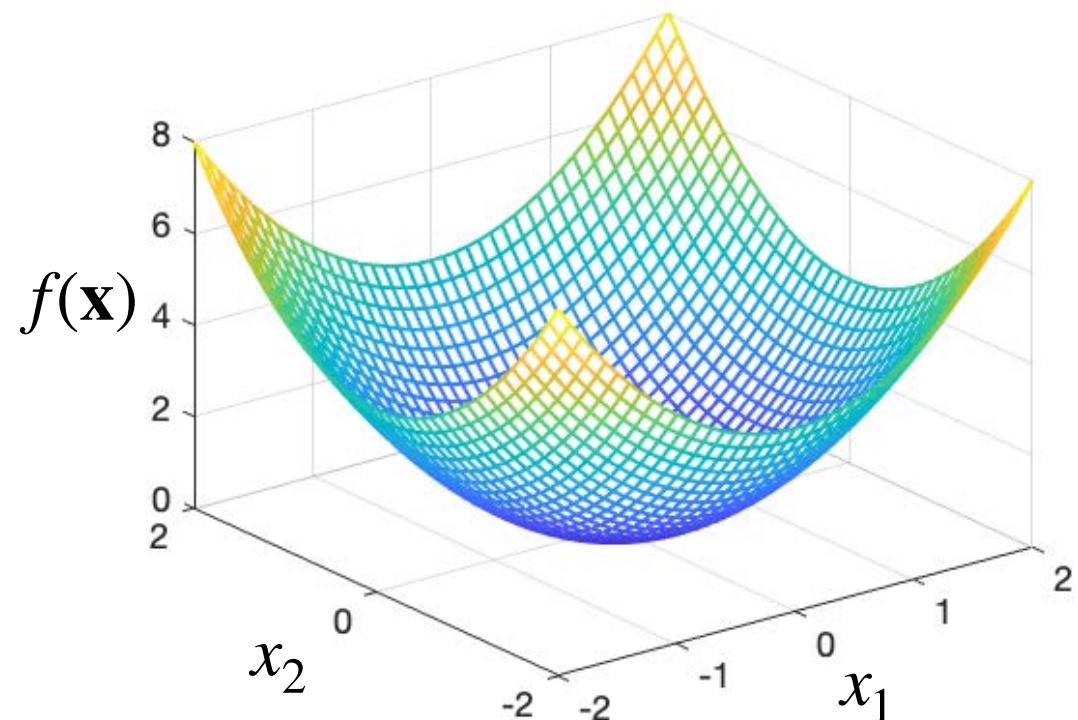

Quadratic Function

$$f(\mathbf{x}) = x_1^2 + x_2^2$$

$$\frac{\partial f}{\partial x_1} = 2x_1$$

$$\frac{\partial f}{\partial x_2} = 2x_2$$

$$\nabla f(\mathbf{x}) = \begin{bmatrix} 2x_1 \\ 2x_2 \end{bmatrix} \in \mathbb{R}^2$$

The color also represents the value of $f(\mathbf{x})$

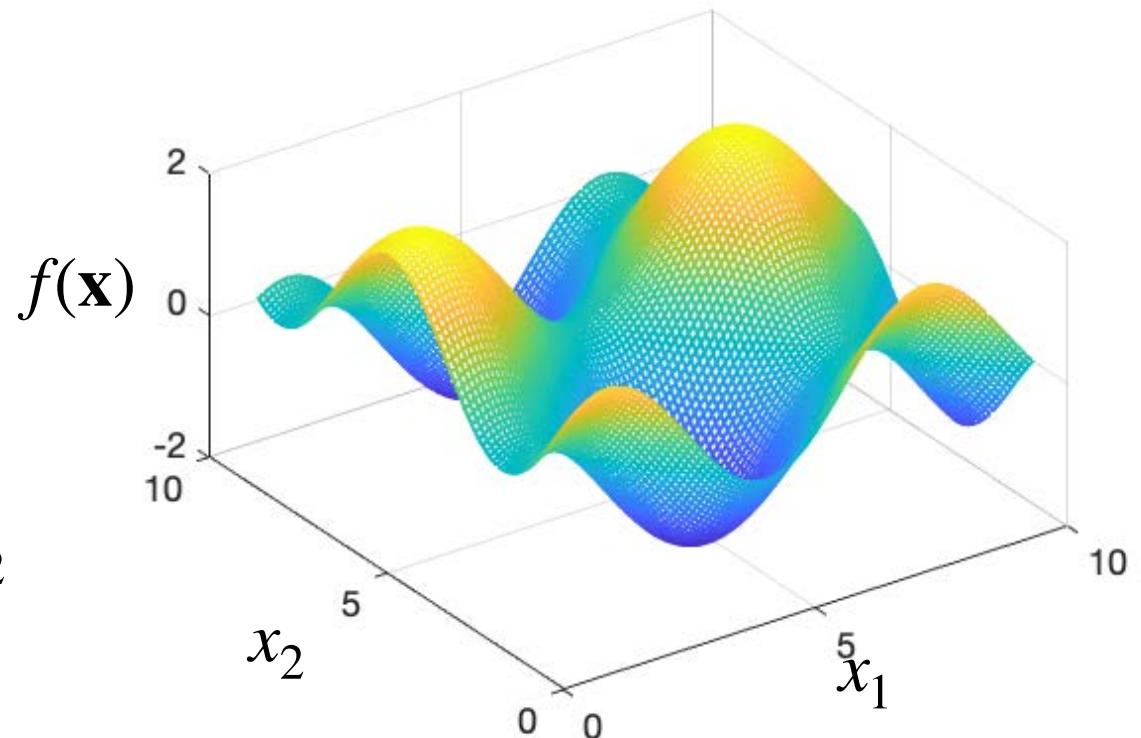

Sinusoidal Function

$$f(\mathbf{x}) = \sin x_1 + \cos x_2$$

$$\frac{\partial f}{\partial x_1} = \cos(x_1)$$

$$\frac{\partial f}{\partial x_2} = -\sin(x_2)$$

$$\nabla f(\mathbf{x}) = \begin{bmatrix} \cos(x_1) \\ -\sin(x_2) \end{bmatrix} \in \mathbb{R}^2$$

The color also represents the value of $f(\mathbf{x})$

Gradient in 4 Dimensions

$$f(\mathbf{x}) = x_1^2 x_2^2 + x_1 x_2 x_3 + x_3 x_4 + 2x_4 + 1$$

$$\frac{\partial f}{\partial x_1} = 2x_1 x_2^2 + x_2 x_3$$

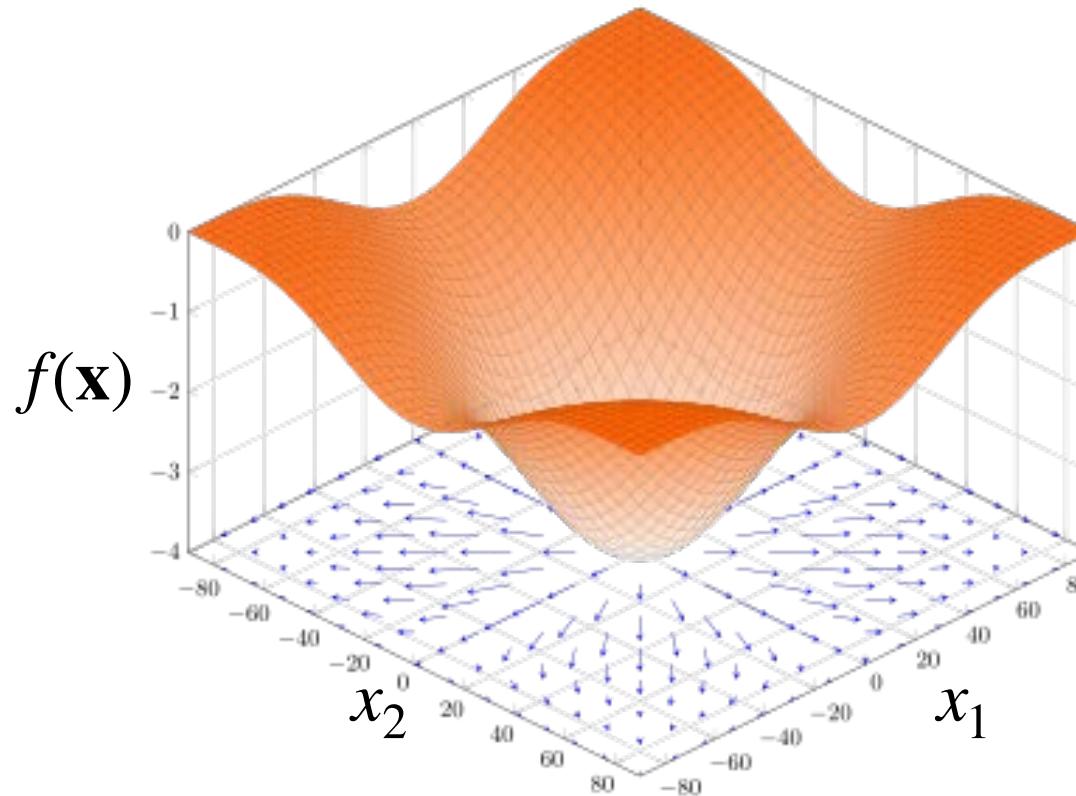

$$\frac{\partial f}{\partial x_2} = 2x_2 x_1^2 + x_1 x_3$$

$$\frac{\partial f}{\partial x_3} = x_1 x_2 + x_4$$

$$\frac{\partial f}{\partial x_4} = x_3 + 2$$

$$\nabla f(\mathbf{x}) = \begin{bmatrix} \frac{\partial f}{\partial x_1} \\ \frac{\partial f}{\partial x_2} \\ \frac{\partial f}{\partial x_3} \\ \frac{\partial f}{\partial x_4} \end{bmatrix} \in \mathbb{R}^4$$

Gradient Properties

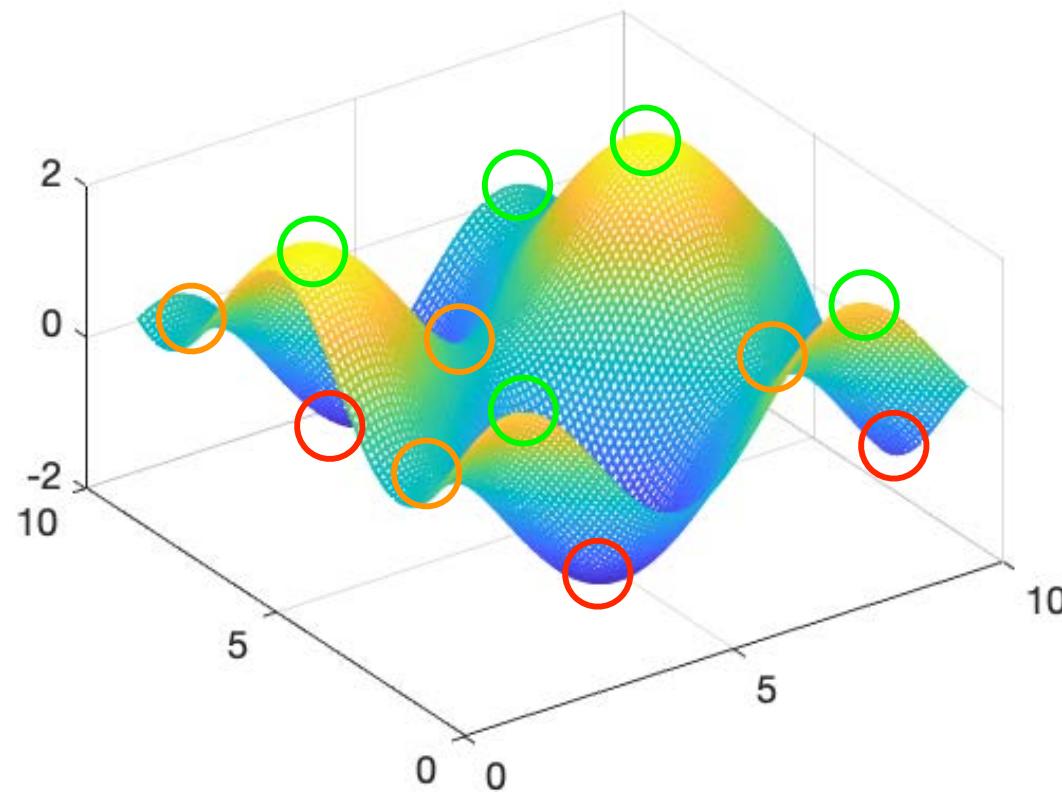

- The gradient at a point \mathbf{x} indicates the direction of greatest increase of the function at \mathbf{x} .
- Its magnitude is the rate of increase in that direction.

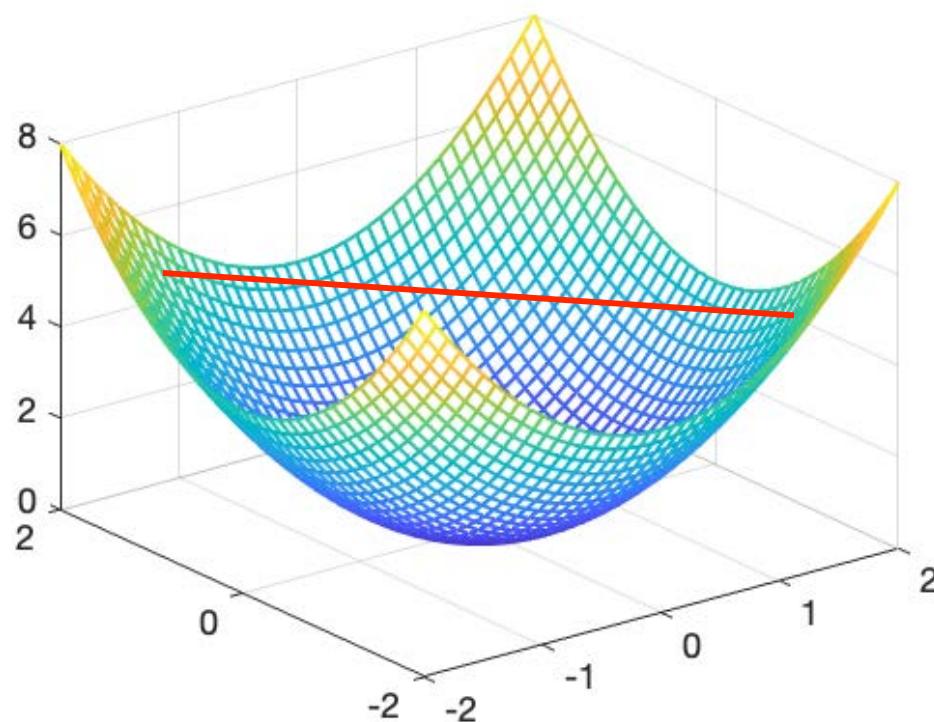

Gradient Properties

The gradient vanishes (becomes a zero vector) at the stationary points of the function:

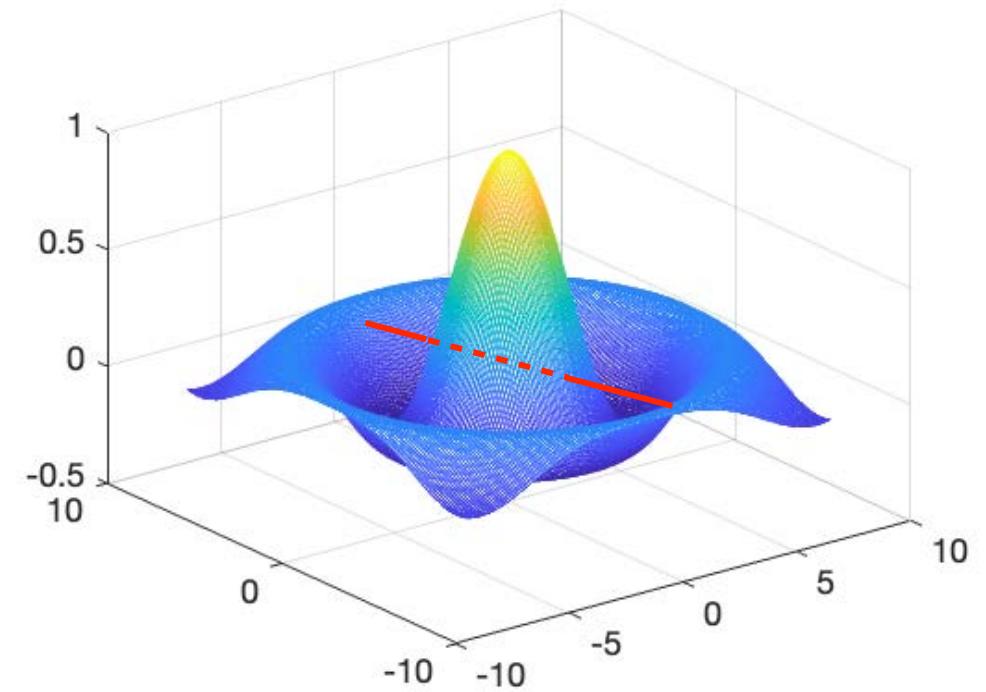

- Minima,
- Maxima,
- Saddle points.

Convex vs Non-Convex

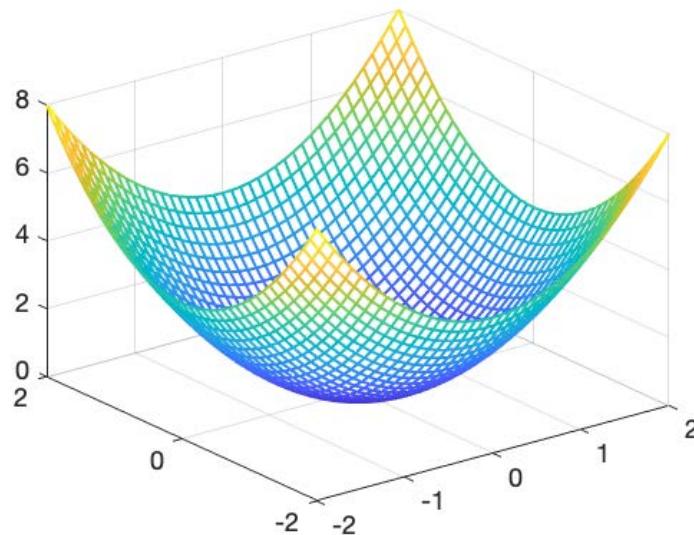

Convex: The line segment between any two points on the function lies above the function

Non-convex: At least one line segment between two points lies in part below the function.

Minimizing a Convex Function

$$\nabla f(\mathbf{x}^*) = \mathbf{0}$$

- Because the gradient is a vector, this yields a system of equations.
- It can still be solved in closed form for some functions.

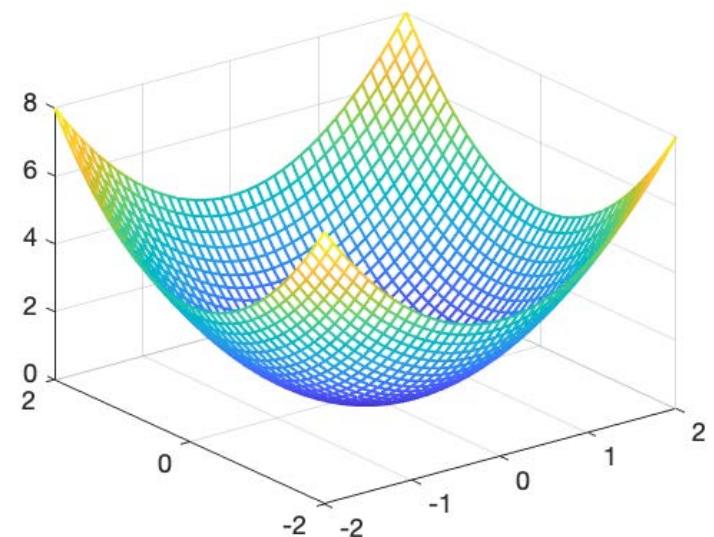

Minimizing a Simple Convex Function

$$f(\mathbf{x}) = x_1^2 + x_2^2$$

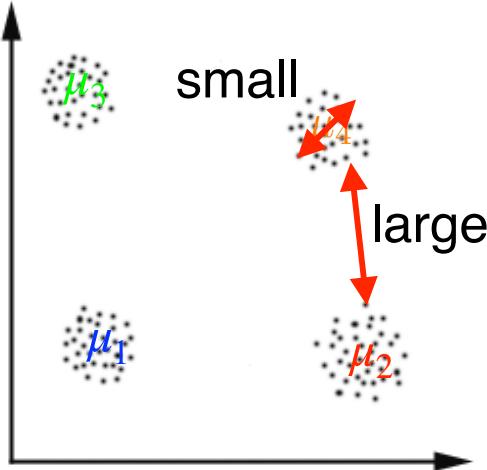

$$\frac{\partial f}{\partial x_1} = 2x_1 \quad \frac{\partial f}{\partial x_2} = 2x_2$$

$$\nabla f(\mathbf{x}) = 0 \Leftrightarrow \begin{cases} 2x_1 = 0 \\ 2x_2 = 0 \end{cases}$$

$$\Leftrightarrow x_1 = x_2 = 0$$

Revisiting K means

- Cluster k is formed by the points $\{\mathbf{x}_{i_1^k}, \dots, \mathbf{x}_{i_{n^k}^k}\}$.
 - μ_k is the **center of gravity** of cluster k .
-
- The distances between the points within a cluster should be small.
 - The distances across clusters should be large.
 - This can be encoded via the distance to cluster centers $\{\mu_1, \dots, \mu_K\}$:

$$\rightarrow \text{Minimize} \sum_{k=1}^K \sum_{j=1}^{n_k} (\mathbf{x}_{i_j^k} - \mu_k)^2$$

where $\{\mathbf{x}_{i_1^k}, \dots, \mathbf{x}_{i_{n^k}^k}\}$ are the n^k samples that belong to cluster k .

Revisiting K means

The minimization problem can be reformulated as:

$$\min_{\{\mu_k\}, \{r_i^k\}} R(\{\mu_k\}, \{r_i^k\}) \text{ with } R = \sum_{i=1}^N \sum_{k=1}^K r_i^k \|\mathbf{x}_i - \mu_k\|^2$$

such that $r_i^k \in \{0,1\}$, $\forall i, k$

and $\sum_{k=1}^K r_i^k = 1$, $\forall i$

—> We will derive the solution by alternating between the two types of variables.

Revisiting K means

$$\min_{\{r_i^k\}} \sum_{i=1}^N \sum_{k=1}^K r_i^k \|\mathbf{x}_i - \mu_k\|^2$$

such that $r_i^k \in \{0,1\}, \forall i, k$

$$\sum_{k=1}^K r_i^k = 1, \forall i$$

- Because of the constraints, for each sample, only one r_i^k can be 1.
- We take it to be the one corresponding to the nearest center:

$$r_i^k = \begin{cases} 1, & \text{if } k = \operatorname{argmin}_j \|\mathbf{x}_i - \mu_j\|^2 \\ 0, & \text{otherwise} \end{cases}$$

Revisiting K means

$$\min_{\{\mu_k\}} \sum_{i=1}^N \sum_{k=1}^K r_i^k \|\mathbf{x}_i - \mu_k\|^2$$

- This can be done by zeroing out the partial derivative for each center:

$$\frac{\partial R}{\partial \mu_k} = 2 \sum_{i=1}^N r_i^k (\mathbf{x}_i - \mu_k) = 0$$

- This yields:

$$\mu_k = \frac{\sum_{i=1}^N r_i^k \mathbf{x}_i}{\sum_{i=1}^N r_i^k}$$

- This corresponds to the mean of the samples assigned to cluster k .

Back to Logistic Regression

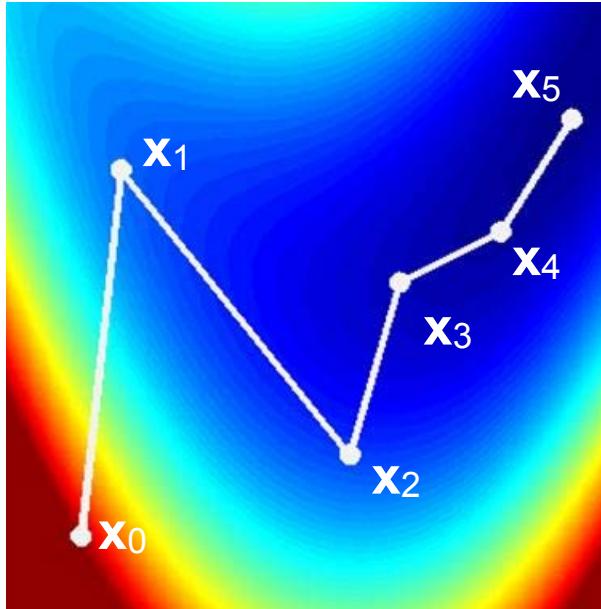

- Replace the step function by a smooth function σ .
- The prediction becomes $y(\mathbf{x}; \tilde{\mathbf{w}}) = \sigma(\tilde{\mathbf{w}} \cdot \tilde{\mathbf{x}})$.
- Given the training set $\{(\mathbf{x}_n, t_n)_{1 \leq n \leq N}\}$ where $t_n \in \{0, 1\}$, minimize the cross-entropy

$$E(\tilde{\mathbf{w}}) = - \sum_n \{t_n \ln y_n + (1 - t_n) \ln(1 - y_n)\}$$
$$y_n = y(\mathbf{x}_n; \tilde{\mathbf{w}})$$

with respect to $\tilde{\mathbf{w}}$.

E is convex but cannot be minimized in closed form!

Gradient Descent

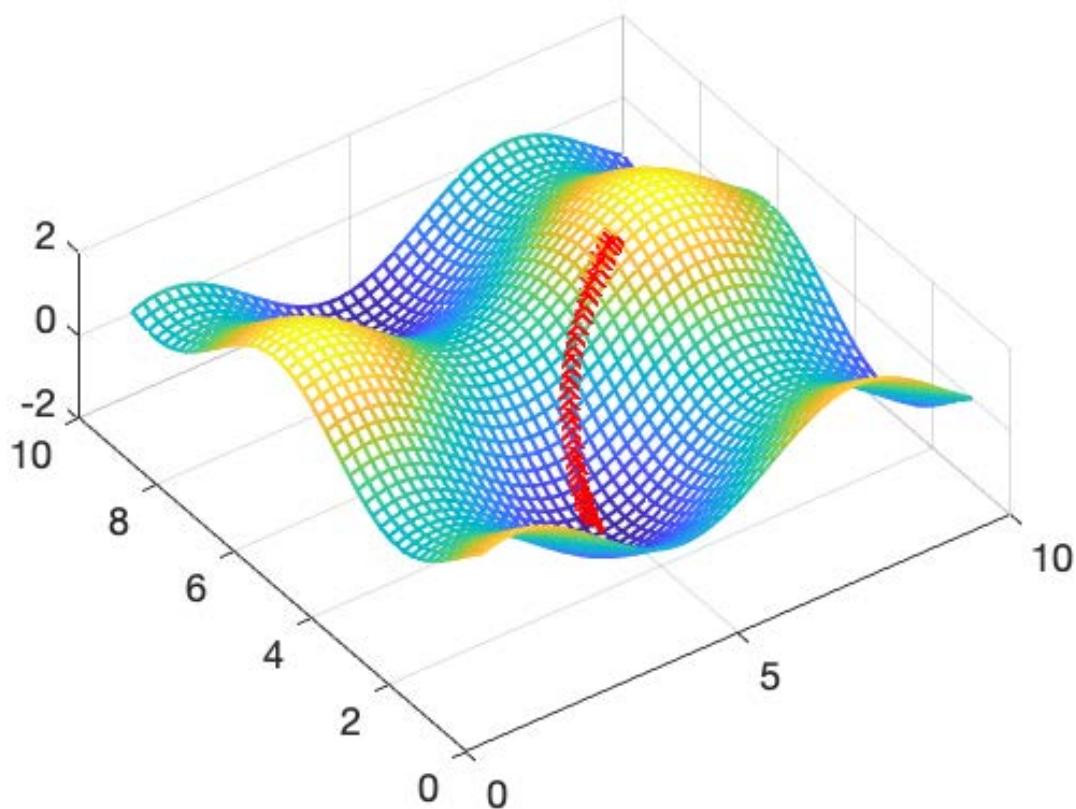

Simplest algorithm:

The gradient replaces the derivative.

1. Initialize \mathbf{x}_0 (e.g., randomly)
2. While not converged
 - 2.1. Update $\mathbf{x}_k \leftarrow \mathbf{x}_{k-1} - \eta \nabla f$

- η defines the step size of each iteration.
- In ML, it is often referred to as the *learning rate*.

Minimizing a Non-convex Function

$$f(\mathbf{x}) = \sin x_1 + \cos x_2$$

$$\nabla f(\mathbf{x}) = \begin{bmatrix} \cos(x_1) \\ -\sin(x_2) \end{bmatrix} \in \mathbb{R}^2$$

Stopping criteria:

- Thresholding the change in function value.
- Thresholding the change in parameters, i.e. $\|\mathbf{x}_{k-1} - \mathbf{x}_k\| < \delta$.

Theoretical Justification

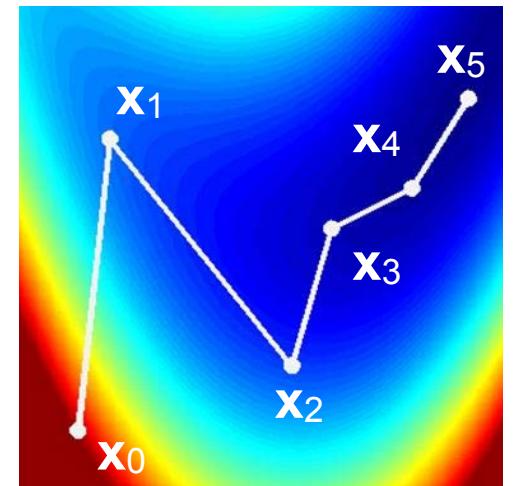

Steepest gradient descent:

$$\mathbf{x}_k \leftarrow \mathbf{x}_{k-1} - \eta \nabla f$$

First order Taylor expansion:

$$f(\mathbf{x} + \mathbf{d}\mathbf{x}) \approx f(\mathbf{x}) + \nabla f(\mathbf{x})^T \mathbf{d}\mathbf{x}$$

$$f(\mathbf{x} - \eta \nabla f(\mathbf{x})) \approx f(\mathbf{x}) - \eta \|\nabla f(\mathbf{x})\|^2 < f(\mathbf{x})$$

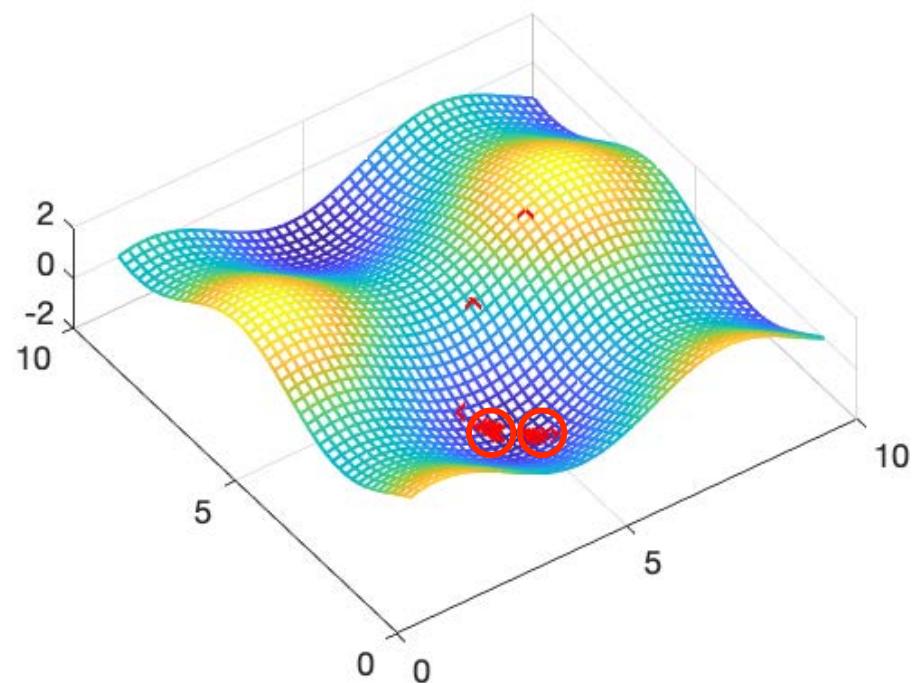

Issues:

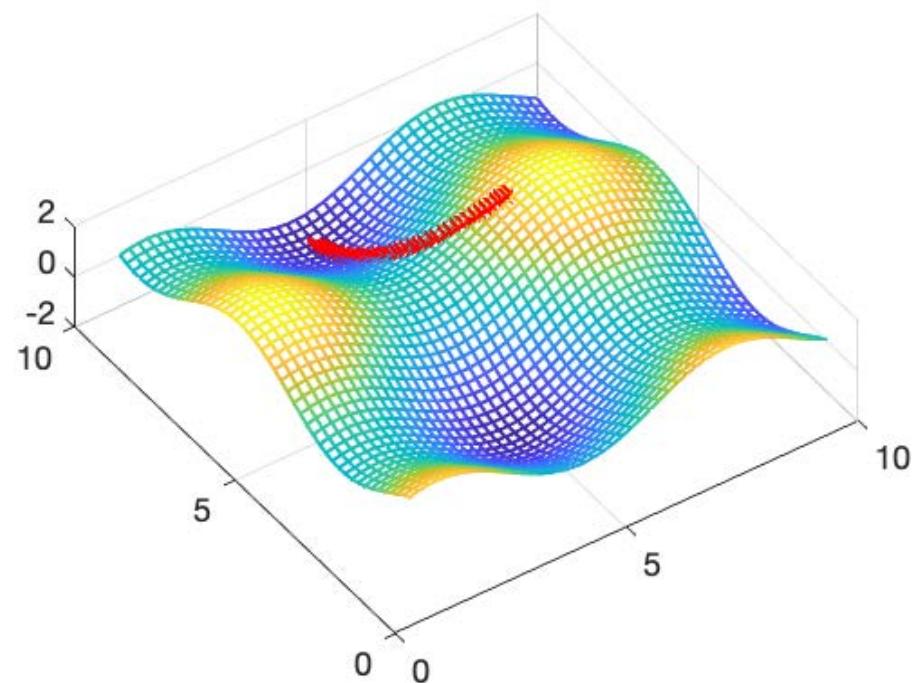

- Justification but no guarantee
- How do we choose η ?
- Many iterations in long and narrow valleys.

Potential Trouble Spots

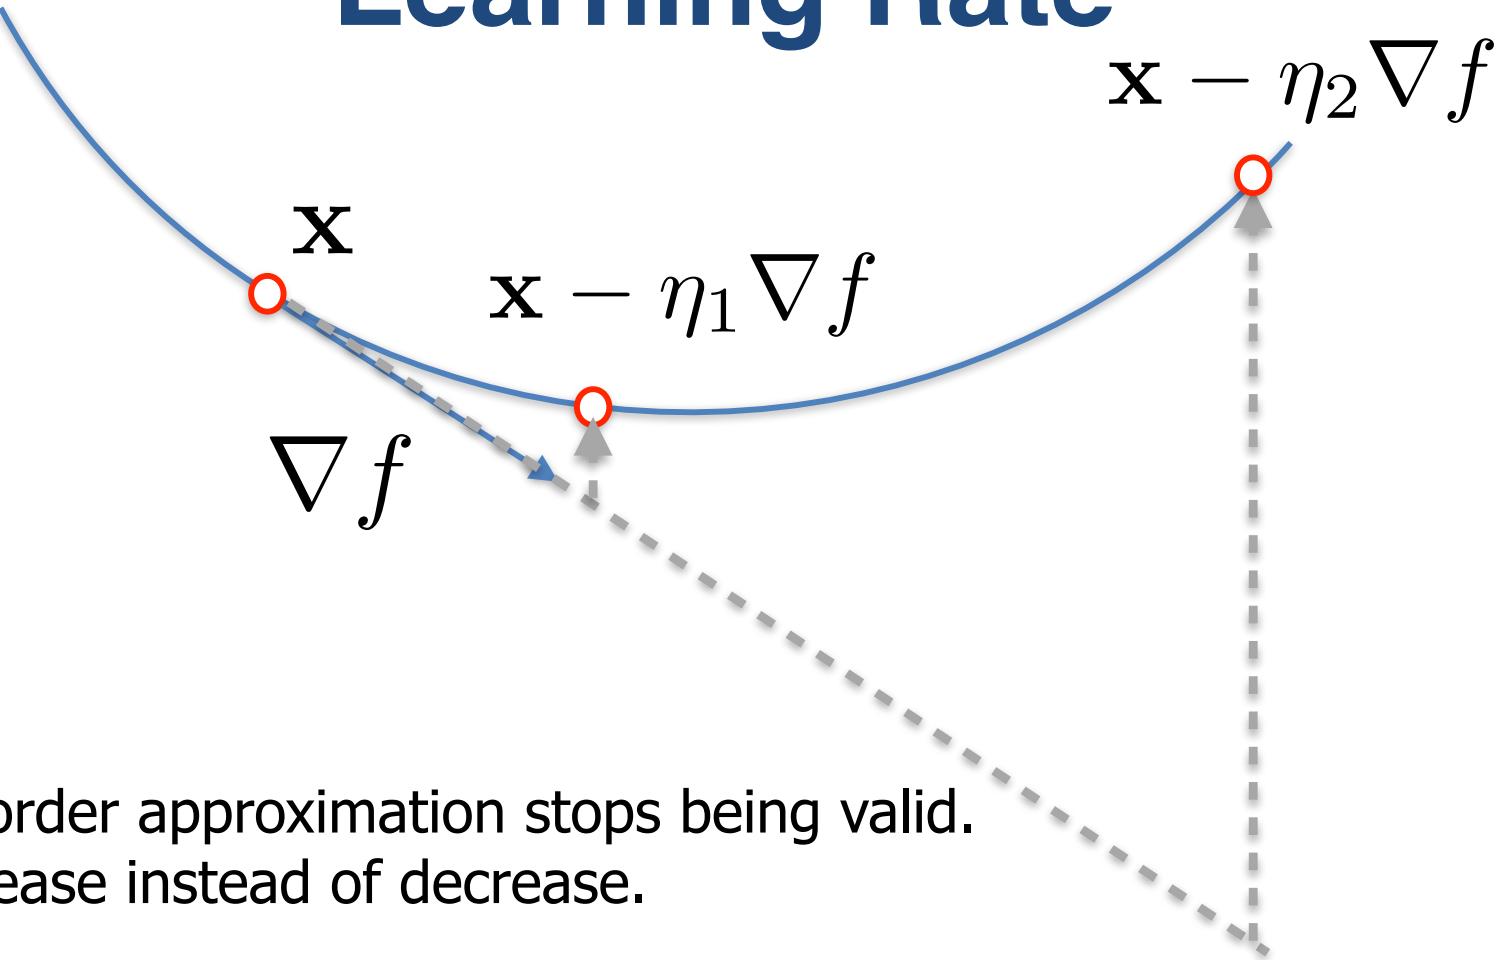

$\eta = 2$ (vs 0.1)
Jumps between 2 solutions

$\mathbf{x}_0 = \begin{bmatrix} 7 \\ 6.5 \end{bmatrix}$ (vs $\begin{bmatrix} 7 \\ 6 \end{bmatrix}$)

Learning Rate

h too large:

- The first order approximation stops being valid.
- f can increase instead of decrease.

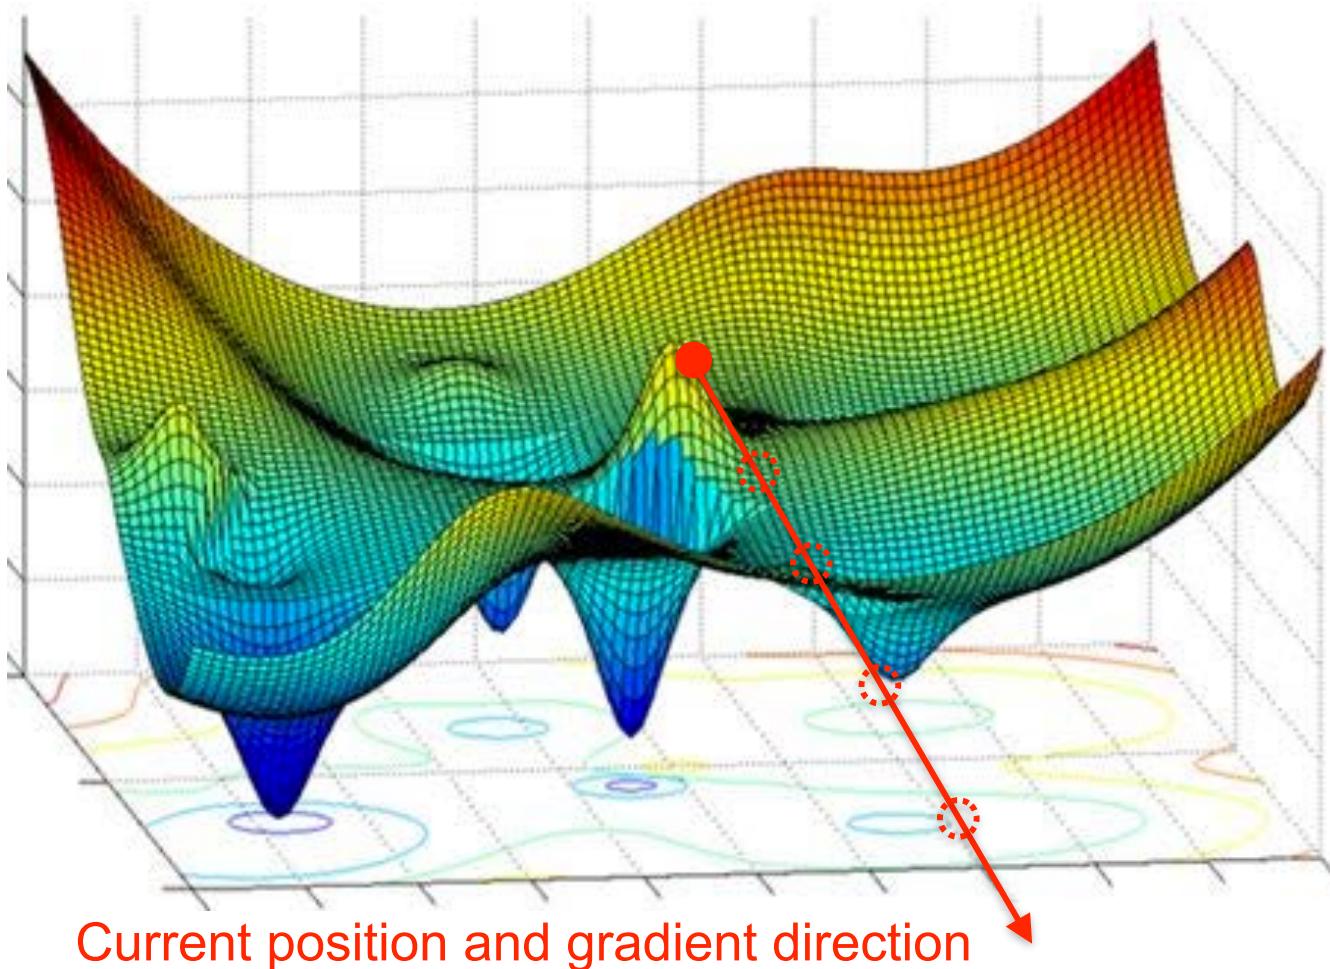

h too small:

- Convergence rate will be very slow.

Partial solution:

- Instead of using a fixed learning rate perform a line search in the direction of the gradient.

Line Search

- Search along the gradient direction for a minimum.
- This is a 1D search and therefore doable.

Python Implementation

```
def steepestGrad(objF,x0,nIt=100,eps=1e-6,step=1.0):
```

```
    for i in range(nIt):
```

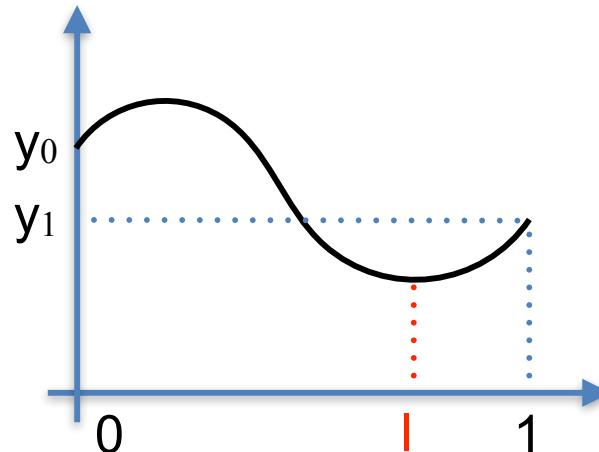

```
        y0,g0=objF(x0)
        x1=x0-step*g0
        y1,_=objF(x1)
        while(y1>y0):
            if(np.allclose(x0,x1,eps)):
                return x0
            step=step/2.0
            x1=x0-step*g0
            y1,_=objF(x1)
```

```
x0,y0=lineSearch(objF,x0,y0,x1,y1,params) #  $\arg \min_{\lambda} \lambda \mathbf{x}_0 + (1 - \lambda) \mathbf{x}_1$ 
```

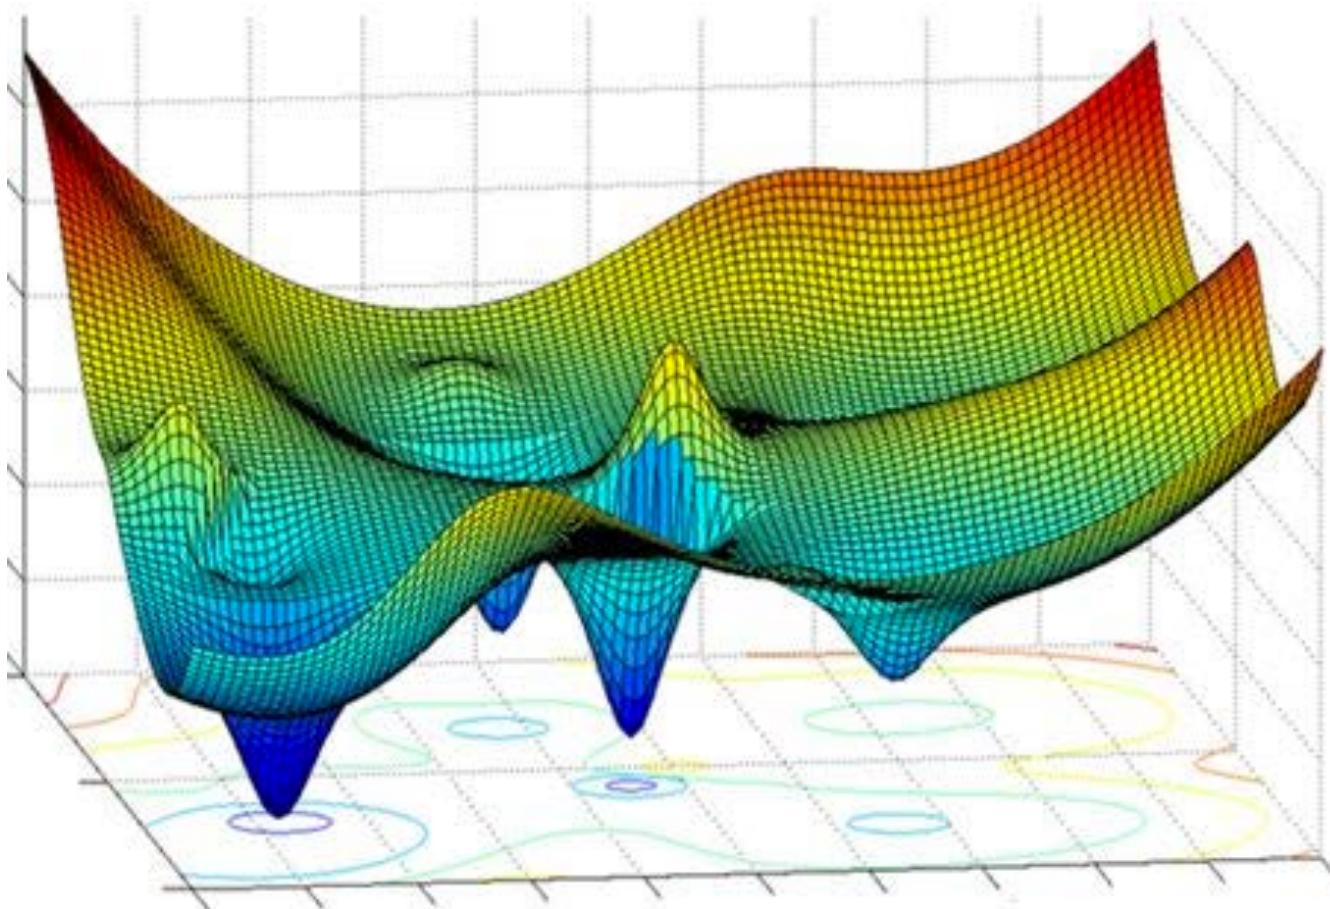

```
return x0
```

```
# Compute the value of objF and its gradient.
# Take a step in the direction of the gradient.
# Compute the new value of objF.
# Check that the function value has decreased.
# Stopping condition.

# Reduce the step size.
# Try again.
```

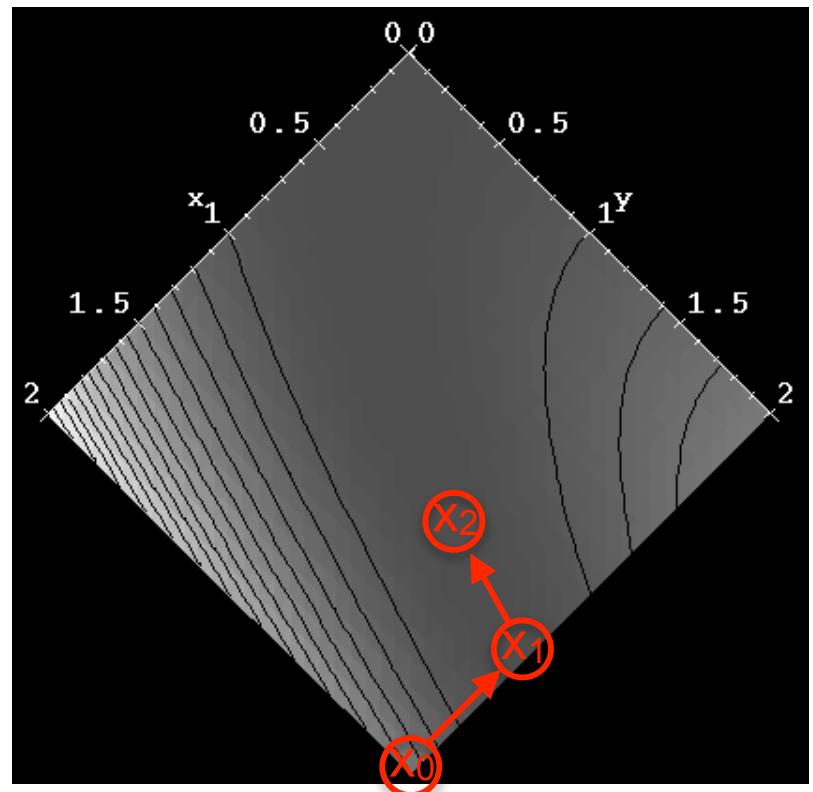

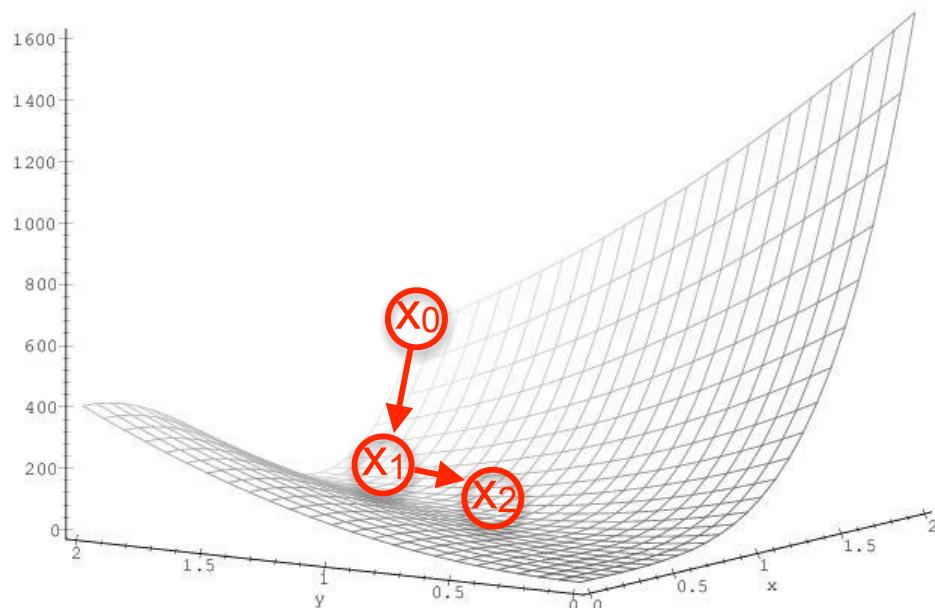

Local Minima

The result depends critically on the starting point and is very likely to be closest local minimum, which is not usually the global one.

Zig-Zagging towards the Solution

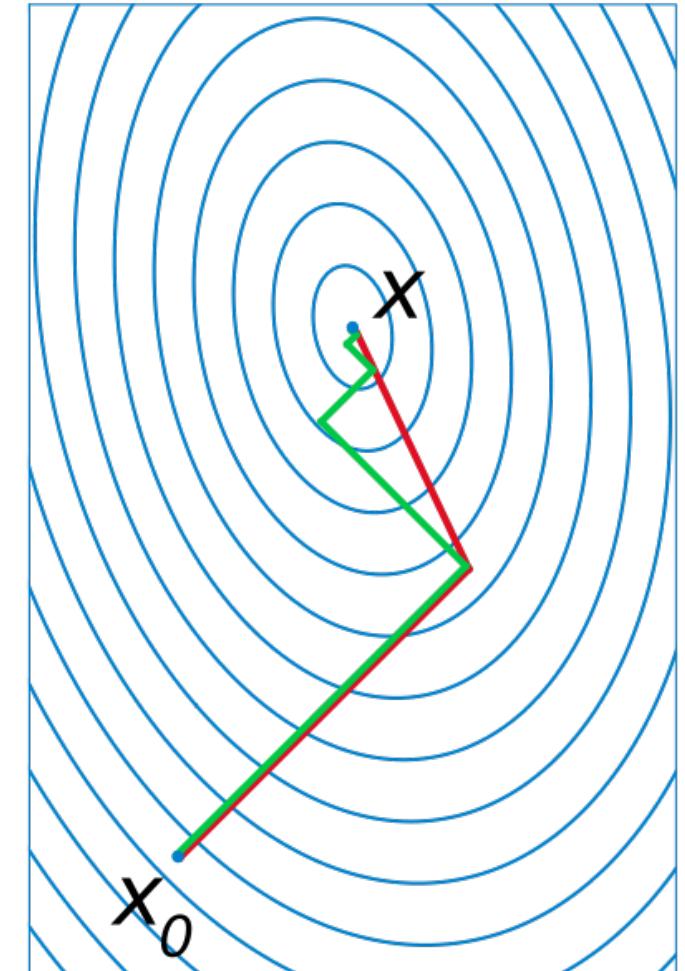

- Successive line searches tend to be perpendicular to each other.
- They would be if we found a true local minimum each time.

Conjugate Gradient

Take the search direction to be a weighted average of the gradient vector and the previous search directions:

1. Start at \mathbf{x}_0 .
2. $\mathbf{g}_0 = \nabla F(\mathbf{x}_0)$.
3. For k from 0 to $n - 1$:
 - (a) Find α_k that minimizes $f(\mathbf{x}_k + \alpha_k \mathbf{g}_k)$.
 - (b) $\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k \mathbf{g}_k$.
 - (c) $\beta_k = \frac{\|\nabla f(\mathbf{x}_{k+1})\|^2}{\|\nabla f(\mathbf{x}_k)\|^2}$.
 - (d) $\mathbf{g}_{k+1} = -\nabla f(\mathbf{x}_{k+1}) + \beta_k \mathbf{g}_k$.
4. $\mathbf{x}_0 = \mathbf{x}_n$ and go to step 2 until convergence.

→ Faster convergence.

Optional: Python Implementation

```
def conjugateGrad(objF,x0,nIt=100,eps=1e-10,step=1.0):

    y0,g0=objF(x0)
    h0=-g0
    g0 =h0
    # g: Function gradient.
    # h: Conjugate direction.

    for i in range(1,nIt):
        l0=np.linalg.norm(h0)
        if(l0<eps):
            print('Gradient has vanished.')
            break
        x1 =x0+(step/l0)*h0
        y1,_=objF(x1)
        while(y1>y0):
            if(np.allclose(x0,x1,eps)):
                return x0
            step=step/2.0
            x1 =x0+(step/np.linalg.norm(h0))*h0
            y1,_=objF(x1,False)

        x1,y1=lineSearch(objF,x0,y0,x1,y1)
        y1,g1=objF(x1)
        g1=-g1
        h1=g1
        # Recompute value and gradient.

        if((i%n)>0):
            gamma=np.dot((g1-g0),g1)/np.dot(g0,g0)
            if(gamma>0):
                h1=g1+gamma*h0
                # Compute conjugate direction but reset every n iterations.
                # Modified Polak Ribiére, i.e. only if gamma > 0.

        # Switch variables
        g0=g1
        h0=h1
        x0=x1
        y0=y1
```

Optional: In Real Life (1)

```
import scipy
```

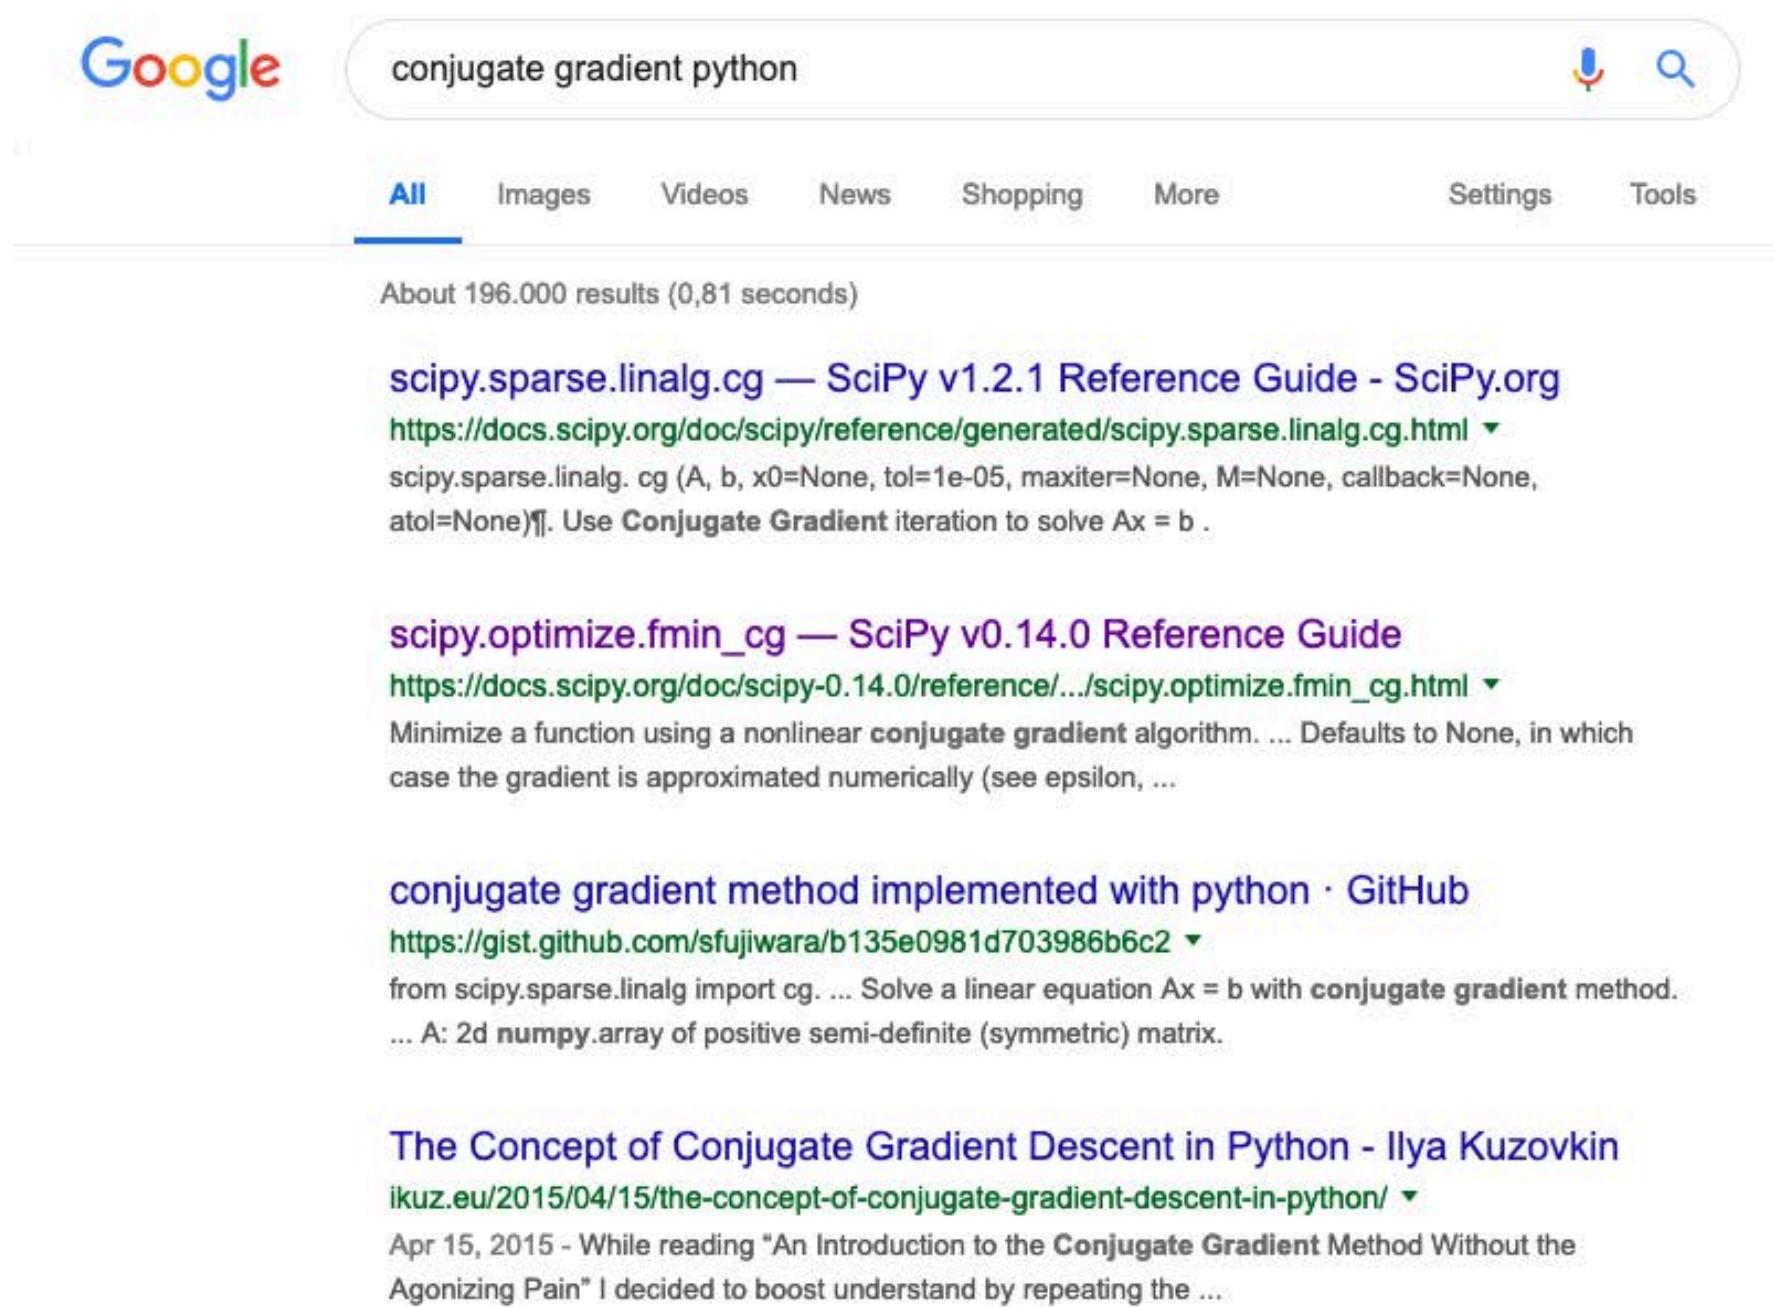

```
def f(x):  
    ..... # return the value of the function.
```

```
def g(x):  
    ..... # return the gradient of the function.
```

```
x0= .... # starting point.
```

```
x1= scipy.optimize.fmin_cg(f,x0,fprime=g,epsilon=eps,maxiter=nIt)
```

Playground

Load a preset... ▾

Assume that f is a function and g its gradient written in python, use conjugate gradient to minimize them.

```
#import necessary packages
import numpy as np
from scipy.optimize import minimize

#define the function and gradient
def f(x):
    return np.sum(x**2)

def g(x):
    return 2*x

#set the initial guess
x0 = np.array([1,2,3])

#minimize using conjugate gradient
res = minimize(f, x0, method='CG', jac=g)

#print out the result
print(res.x)
```

Optional: Second Order Methods

Second order Taylor expansion:

$$f(\mathbf{x} + \mathbf{d}\mathbf{x}) \approx f(\mathbf{x}) + \nabla f(\mathbf{x})^T \mathbf{d}\mathbf{x} + \frac{1}{2} \mathbf{d}\mathbf{x}^T H(\mathbf{x}) \mathbf{d}\mathbf{x}$$

$$\nabla f(\mathbf{x} + \mathbf{d}\mathbf{x}) \approx \nabla f(\mathbf{x}) + H(\mathbf{x}) \mathbf{d}\mathbf{x}$$

Newton method:

$$\text{Solve } H(\mathbf{x}) \mathbf{d}\mathbf{x} = -\nabla f(\mathbf{x})$$

$$\Rightarrow \mathbf{d}\mathbf{x} = -H(\mathbf{x})^{-1} \nabla f(\mathbf{x})$$

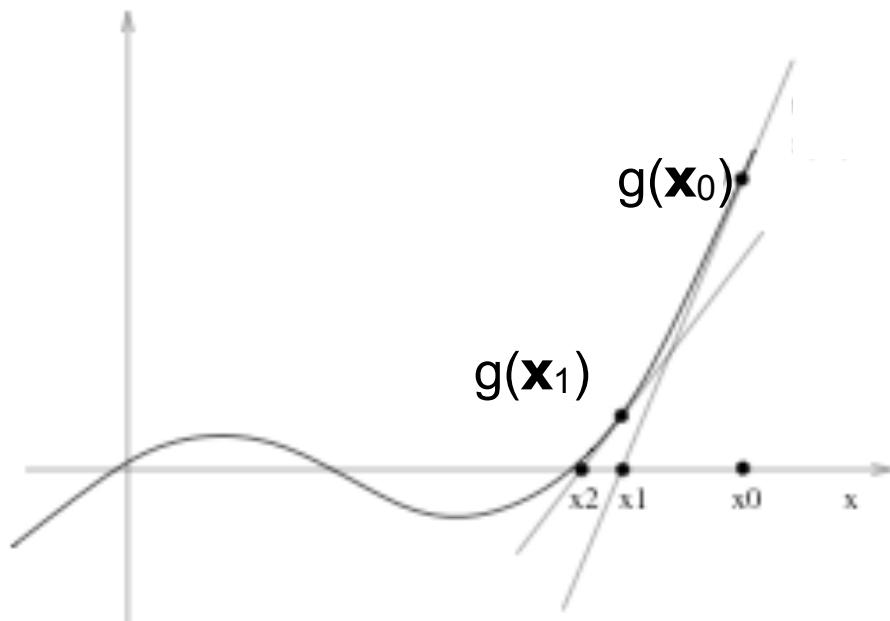

$$\nabla f(\mathbf{x} + \mathbf{d}\mathbf{x}) \approx 0$$

$$\begin{aligned} f(\mathbf{x} + \mathbf{d}\mathbf{x}) &\approx f(\mathbf{x}) - \nabla f(\mathbf{x})^T H(\mathbf{x})^{-1} \nabla f(\mathbf{x}) \\ &\quad + \frac{1}{2} \nabla f(\mathbf{x})^T H(\mathbf{x})^{-1} \cancel{H(\mathbf{x})} \cancel{H(\mathbf{x})^{-1}} \nabla f(\mathbf{x}) \\ &\approx f(\mathbf{x}) - \frac{1}{2} \nabla f(\mathbf{x})^T H(\mathbf{x})^{-1} \nabla f(\mathbf{x}) \end{aligned}$$

Optional: Newton in 1D

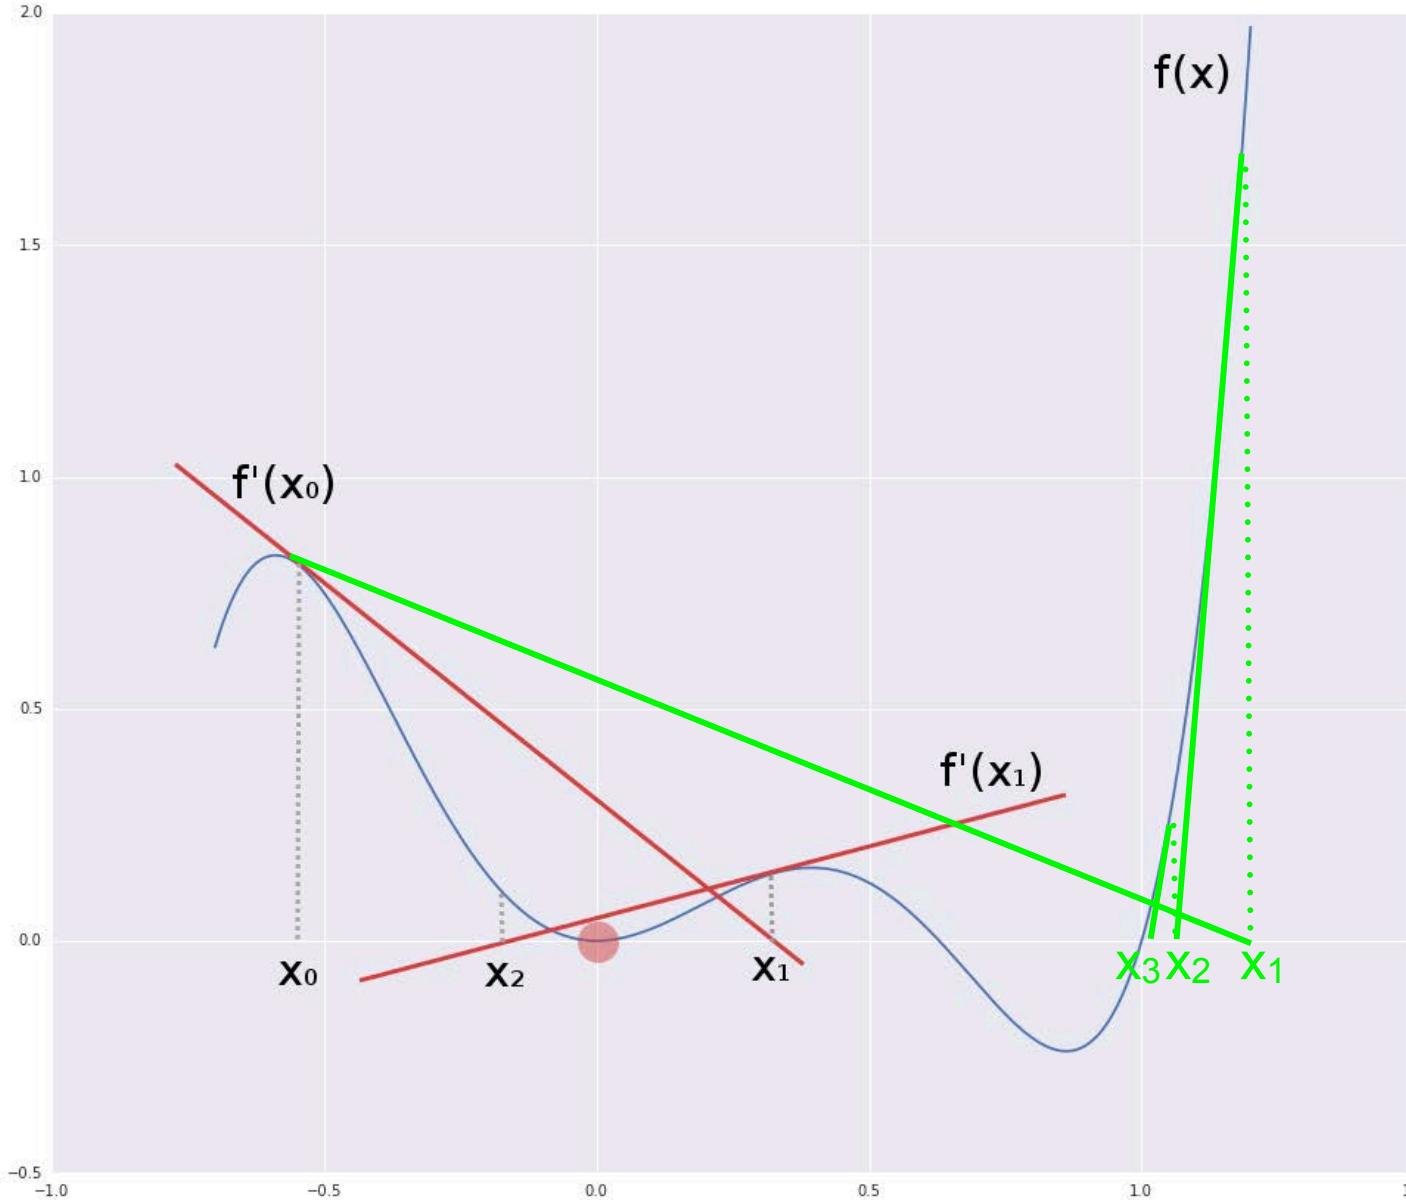

$$0 = g(x + dx) = g(x) + g'(x)dx$$

$$\Rightarrow dx = -\frac{g(x)}{g'(x)}$$

$$x \leftarrow x - \frac{g(x)}{g'(x)}$$

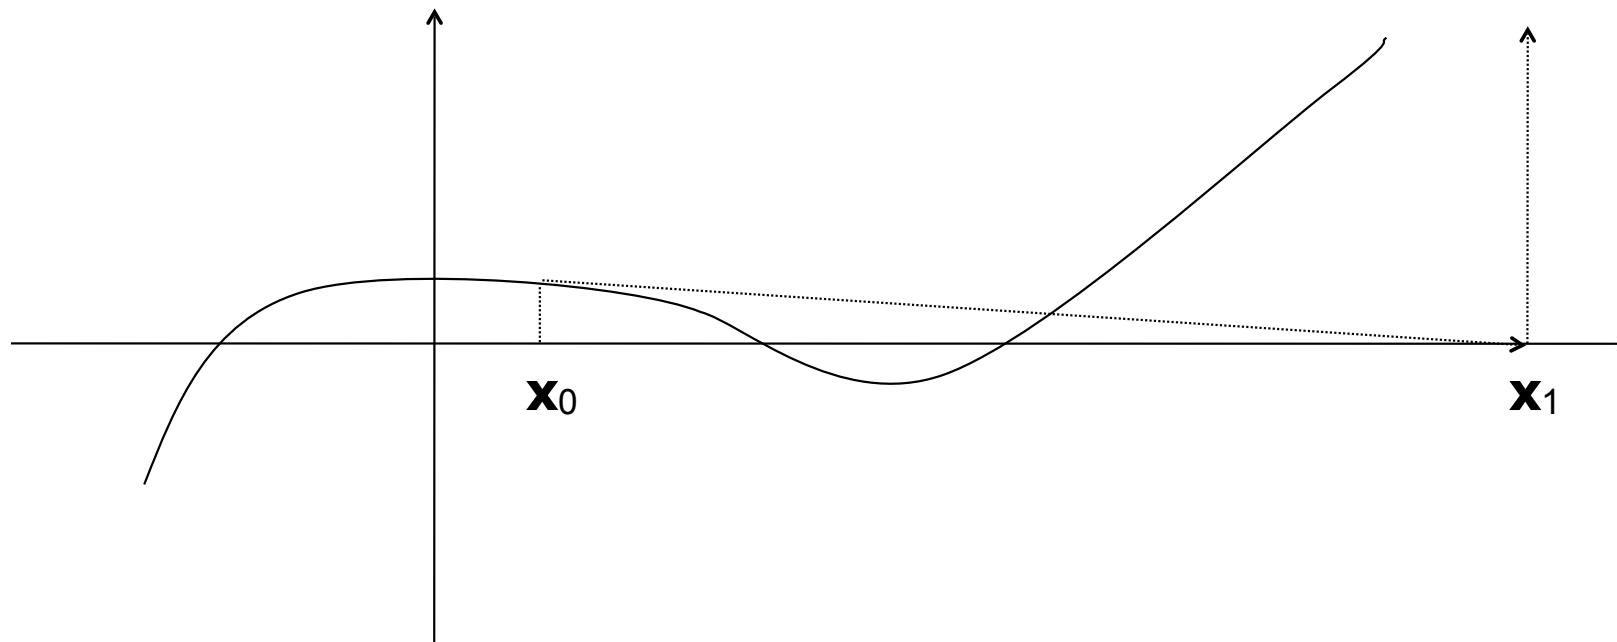

Optional: Finding Polynomial Roots

$$f(x) = 6x^5 - 5x^4 - 4x^3 + 3x^2$$

- There is more than one root.
- The one you find depends on the starting point.

Optional: Potential Instability

- Individual steps can be very large, leading to instability.

Optional: Damped Newton

Second order Taylor expansion:

$$f(\mathbf{x} + \mathbf{d}\mathbf{x}) \approx f(\mathbf{x}) + \nabla f(\mathbf{x})^T \mathbf{d}\mathbf{x} + \frac{1}{2} \mathbf{d}\mathbf{x}^T H(\mathbf{x}) \mathbf{d}\mathbf{x}$$

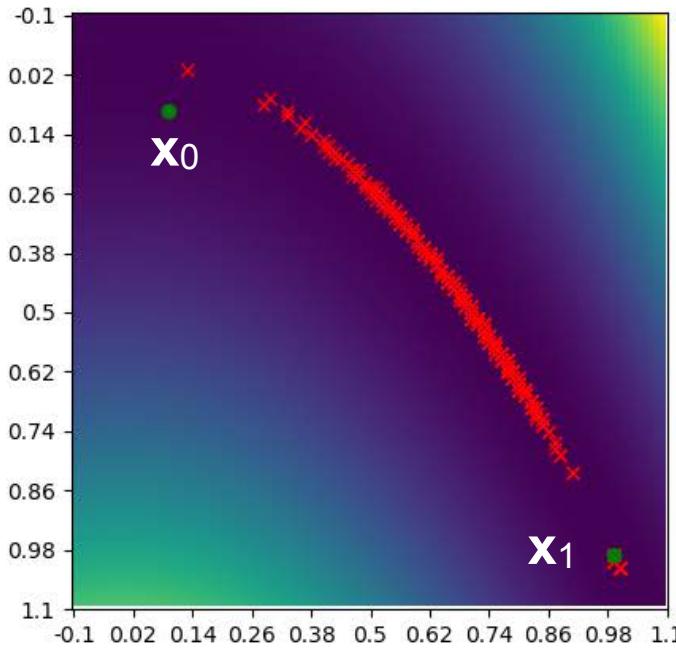

$$\nabla f(\mathbf{x} + \mathbf{d}\mathbf{x}) \approx \nabla f(\mathbf{x}) + H(\mathbf{x}) \mathbf{d}\mathbf{x}$$

Introduce a damping term:

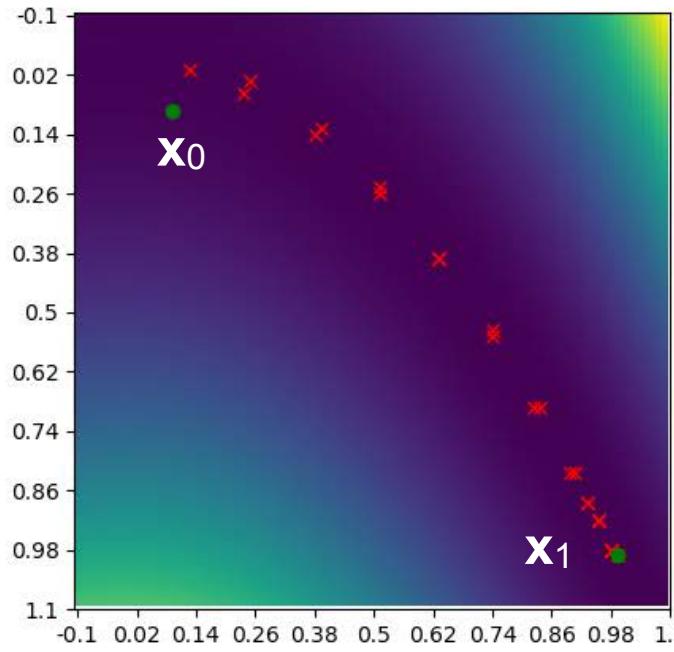

$$\mathbf{x} \leftarrow \mathbf{x} + \mathbf{d}\mathbf{x} \text{ with } \begin{cases} \text{Regular Newton Method: } H(\mathbf{x}) \mathbf{d}\mathbf{x} = -\nabla f(\mathbf{x}) \\ \text{Damped Newton: } (H(\mathbf{x}) + \lambda \mathbf{I}) \mathbf{d}\mathbf{x} = -\nabla f(\mathbf{x}) \end{cases}$$

- $\lambda = 0$: Regular Newton
- $\lambda \gg 0$: Gradient descent

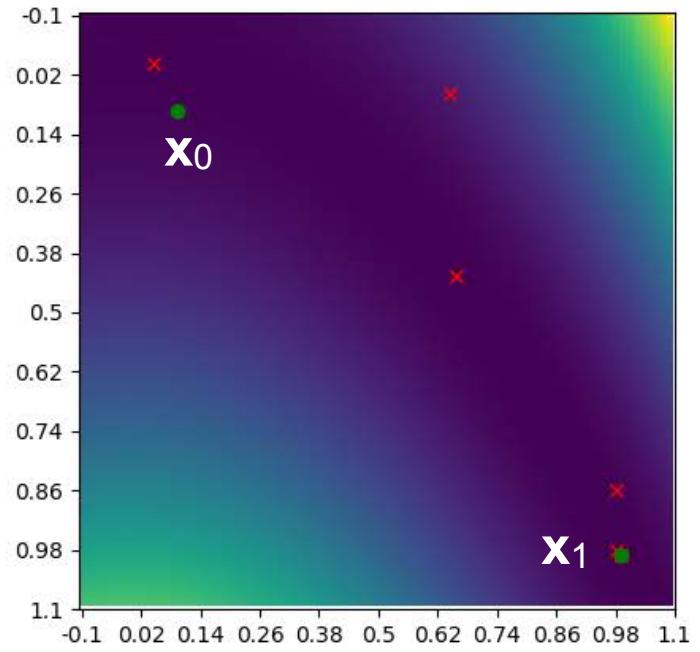

Optional: Qualitative Comparison

Steepest gradient

Conjugate gradient

Damped Newton

Damped Newton converges much faster!

Optional: Python Implementation

```
def dampedNewton(objF,x,nIt=10,lbda=None):  
  
    for i in range(nIt):  
        f,g,H=objF(x)                      # Evaluate f, its gradient, and its Hessian.  
        x -= linSolve(H,g,lbda=lbda)         # Solve  $(H + \lambda I)x = g$   
    return x  
  
def linSolve(A,b,lbda=None):  
  
    if(lbda is not None):  
        A=A+lbda*np.eye(A.shape[0]) #  $A \leftarrow A + \lambda I$   
    x=np.linalg.solve(A,b)           # Solve  $Ax = b$   
    return(x)
```

Back to Maximizing the Margin

$$\mathbf{w}^* = \operatorname{argmin}_{(\mathbf{w}, \{\xi_n\})} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_{n=1}^N \xi_n,$$

subject to $\forall n, t_n \cdot (\tilde{\mathbf{w}} \cdot \mathbf{x}_n) \geq 1 - \xi_n$ and $\xi_n \geq 0$.

- C is constant that controls how costly constraint violations are.
- The problem is still convex.

—> Minimization under constraints.

Adding Constraints

- In general, a constrained optimization problem can then be written as:

$$\min_{\mathbf{x}} f(\mathbf{x})$$

subject to $f_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, M$ (M inequality constraints)

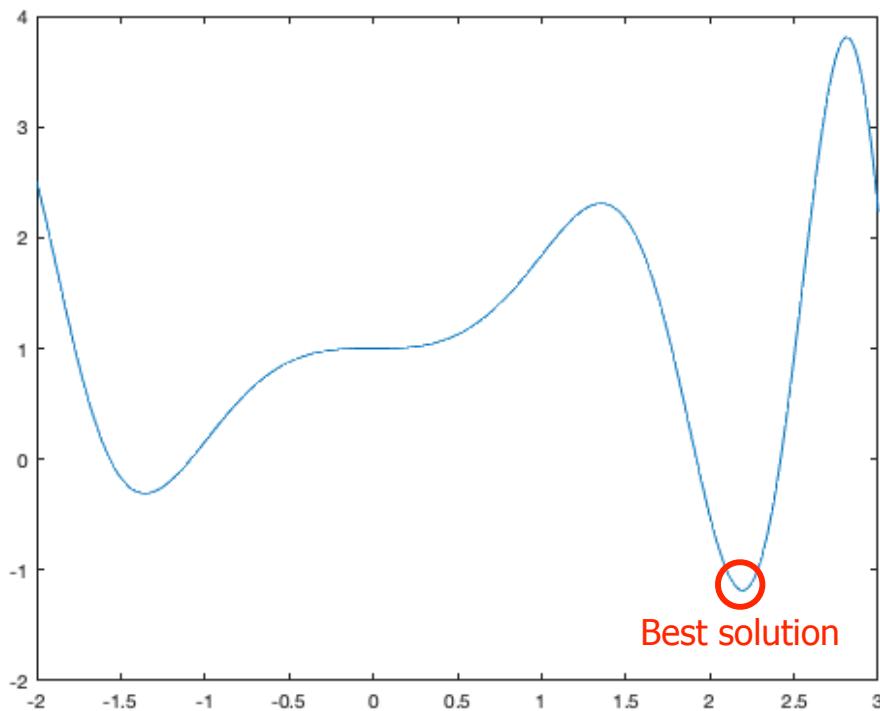

$h_i(\mathbf{x}) = 0, \quad i = 1, \dots, P$ (P equality constraints)

- Note that the constrained problem will typically not have the same solution as the unconstrained one.

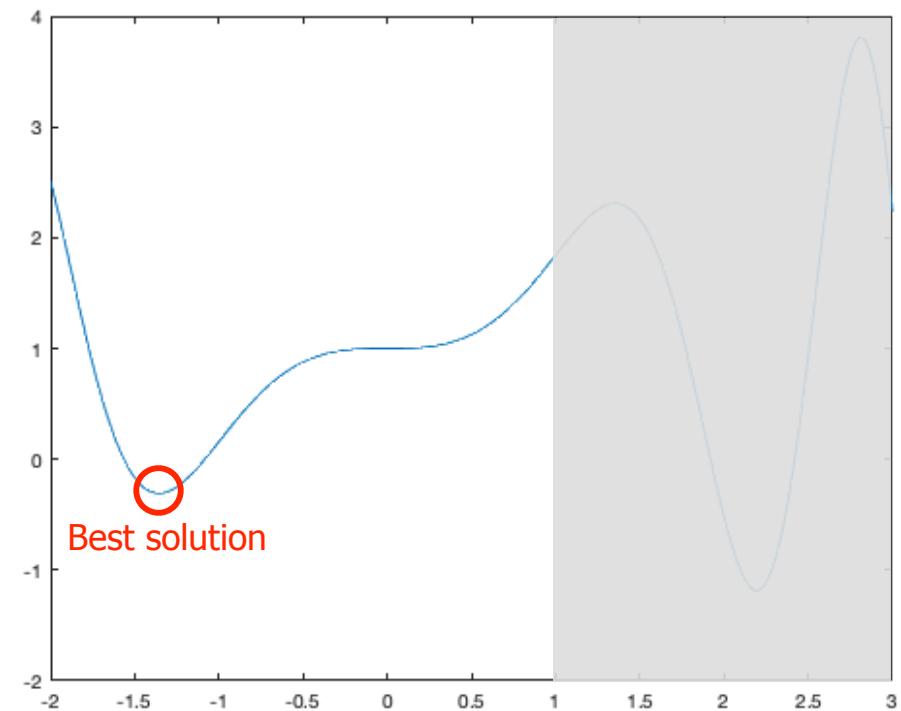

Adding Constraints: Example

$$f(x) = x \sin(x^2) + 1$$

Unconstrained

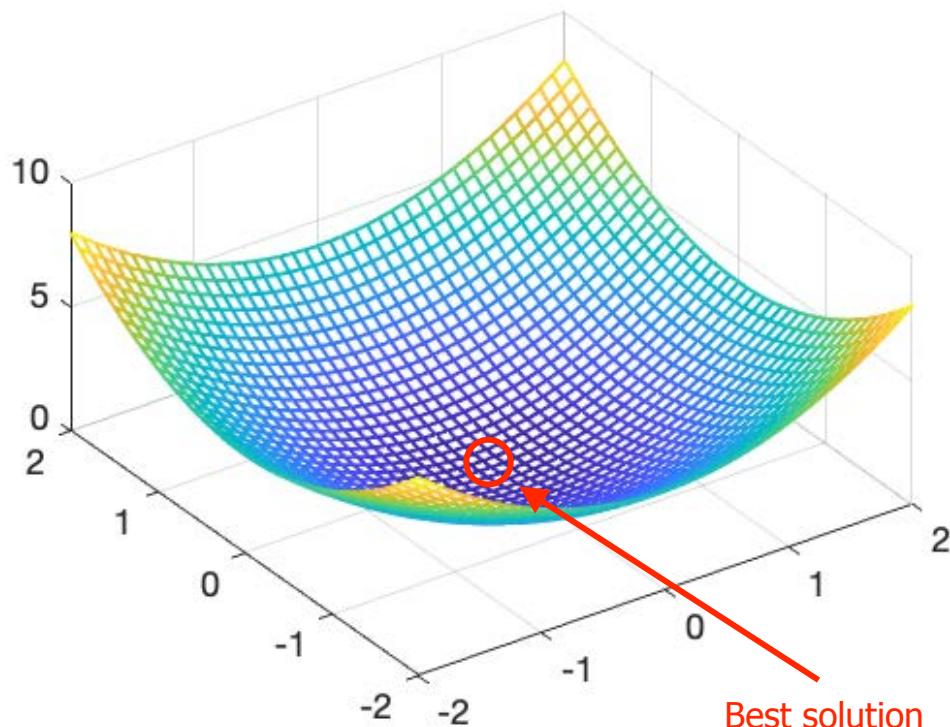

Constrained
 $f_1(x) = x - 1 \leq 0$

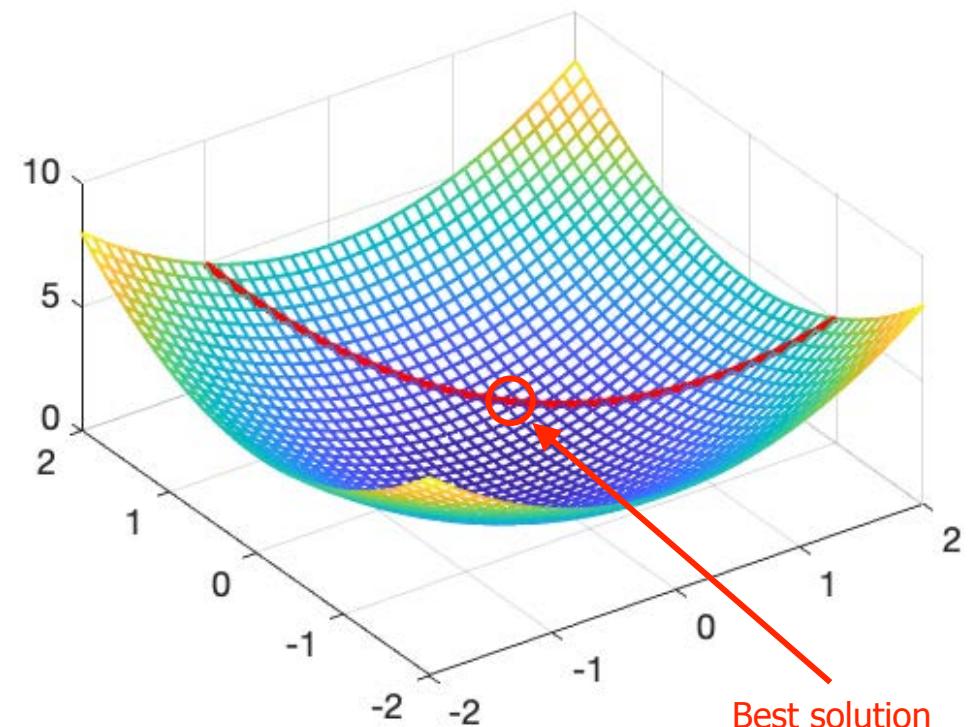

Adding Constraints: Example

$$f(\mathbf{x}) = x_1^2 + x_2^2$$

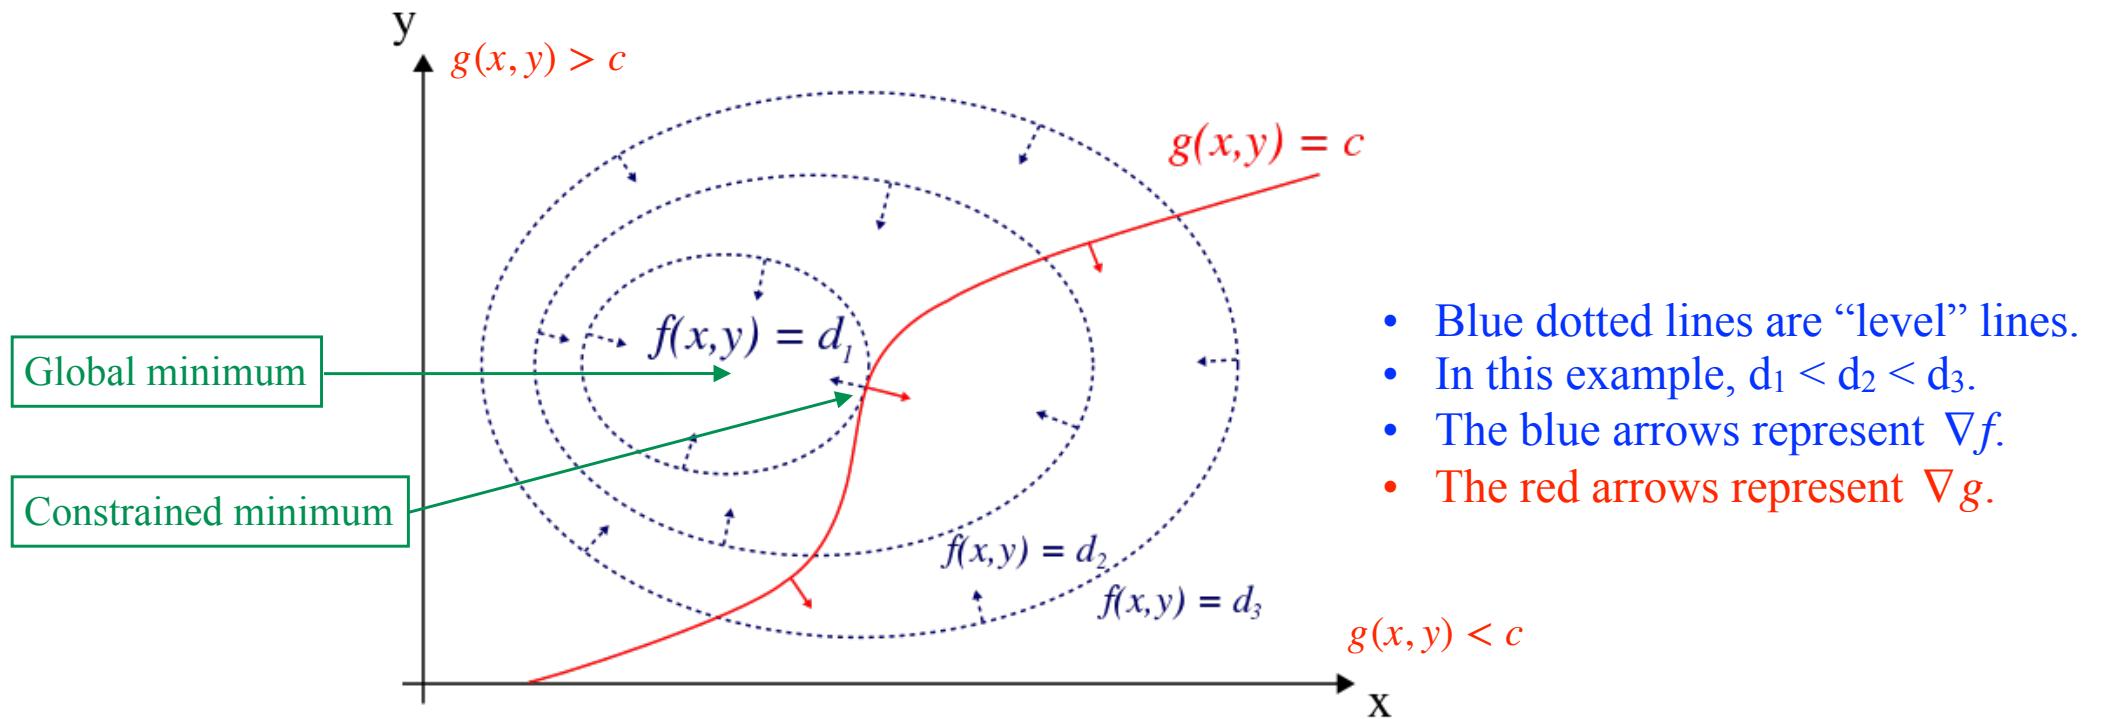

Unconstrained

Constrained
 $h_1(x) = x_1 + x_2 - 1 = 0$

Implicit Function Theorem

- Minimize $f(x, y)$ subject to $g(x, y) \leq c$.
- At the constrained minimum
$$\exists \lambda \in R, \nabla f = \lambda \nabla g$$
- λ is known as a Lagrange multiplier.

Lagrangian

$$\min_{\mathbf{x}} f(\mathbf{x})$$

$$\text{subject to } f_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, M$$

$$h_i(\mathbf{x}) = 0, \quad i = 1, \dots, P$$

The Lagrangian is taken to be:

$$L(\mathbf{x}, \lambda, \nu) = f(\mathbf{x}) + \sum_{i=1}^M \lambda_i f_i(\mathbf{x}) + \sum_{i=1}^P \nu_i h_i(\mathbf{x})$$

- λ_i is the Lagrange multiplier associated with $f_i(\mathbf{x}) \leq 0$
- ν_i is the Lagrange multiplier associated with $h_i(\mathbf{x}) = 0$

Lagrangian

$$\min_{\mathbf{x}} f(\mathbf{x})$$

$$\text{subject to } f_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, M$$

$$h_i(\mathbf{x}) = 0, \quad i = 1, \dots, P$$

$$L(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\nu}) = f(\mathbf{x}) + \sum_{i=1}^M \lambda_i f_i(\mathbf{x}) + \sum_{i=1}^P \nu_i h_i(\mathbf{x})$$

A solution of the constrained minimization problem must be such that L is minimized with respect to the components of vector \mathbf{w} and maximized with respect to the Lagrange multipliers, which must remain greater or equal to zero.

KKT Conditions

$$\min_{\mathbf{x}} f(\mathbf{x})$$

subject to $f_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, M$
 $h_i(\mathbf{x}) = 0, \quad i = 1, \dots, P$

$$L(\mathbf{x}, \lambda, \nu) = f(\mathbf{x}) + \sum_{i=1}^M \lambda_i f_i(\mathbf{x}) + \sum_{i=1}^P \nu_i h_i(\mathbf{x})$$

At the minimum

$$\nabla_{\mathbf{x}} L = 0$$

$$\nabla_{\lambda} L = 0 \quad \text{System of equations that can be solved.}$$

$$\nabla_{\nu} L = 0$$

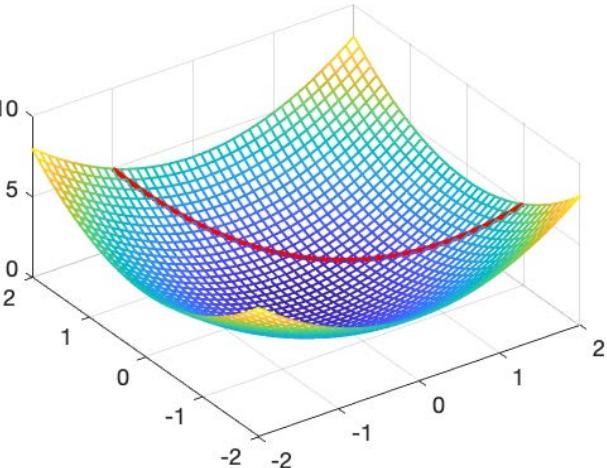

$$\lambda_i f_i(\mathbf{x}_i) = 0 \quad i = 1, \dots, M$$

Example 1

$$\min_{\mathbf{x}} x_1^2 + x_2^2$$

subject to $x_1 + x_2 - 1 = 0$

$$L(\mathbf{x}, \nu_1) = x_1^2 + x_2^2 + \nu_1 (x_1 + x_2 - 1)$$

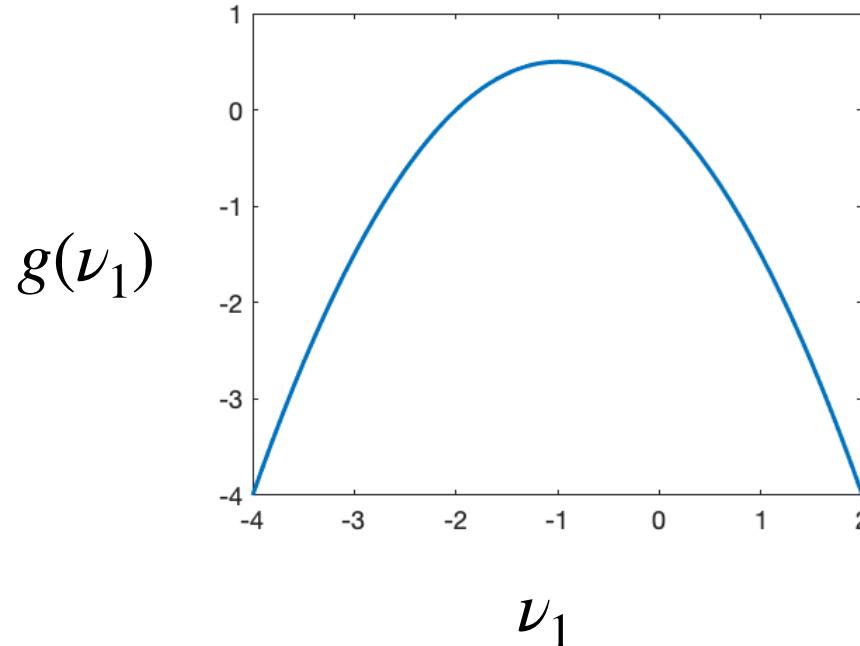

At the minimum:

$$\nabla_{\mathbf{x}} L(\mathbf{x}, \nu_1) = \begin{bmatrix} 2x_1 + \nu_1 \\ 2x_2 + \nu_1 \end{bmatrix} = \mathbf{0} \Leftrightarrow \mathbf{x}^* = \begin{bmatrix} -\nu_1/2 \\ -\nu_1/2 \end{bmatrix}$$

Example 1

$$\begin{aligned} g(\nu_1) &= L \left(\begin{bmatrix} -\nu_1/2 \\ -\nu_1/2 \end{bmatrix}, \nu_1 \right) = \frac{1}{4}\nu_1^2 + \frac{1}{4}\nu_1^2 + \nu_1 \left(-\frac{1}{2}\nu_1 - \frac{1}{2}\nu_1 - 1 \right) \\ &= -\frac{1}{2}\nu_1^2 - \nu_1 \end{aligned}$$

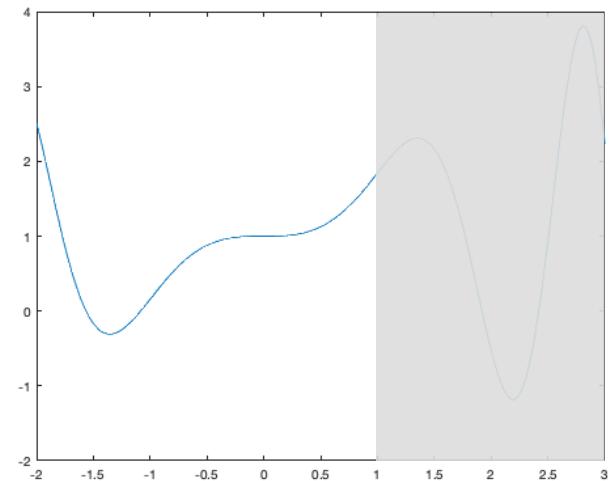

- We can find that maximizes g : $\nu_1 = -1.0$.
- In turn this gives us $\mathbf{x}^* = \begin{bmatrix} -\nu_1/2 \\ -\nu_1/2 \end{bmatrix} = \begin{bmatrix} 0.5 \\ 0.5 \end{bmatrix}$.

Example 2

$$\begin{aligned} \min_x \quad & x \sin(x^2) + 1 \\ \text{subject to} \quad & x - 1 \leq 0 \end{aligned}$$

$$L(x, \lambda_1) = x \sin(x^2) + 1 + \lambda_1 (x - 1)$$

There is no closed form solution to the minimization of L w.r.t. x .

- We write
$$\begin{aligned} g(\lambda_1) &= \min_x L(x, \lambda_1) \\ &= \min_x x \sin(x^2) + 1 + \lambda_1 (x - 1) \end{aligned}$$
- We maximize w.r.t. λ_1

Lagrange Dual Function

$$\begin{aligned} g(\lambda, \nu) &= \inf_{\mathbf{x}} L(\mathbf{x}, \lambda, \nu) \\ &= \inf_{\mathbf{x}} \left(f(\mathbf{x}) + \sum_{i=1}^M \lambda_i f_i(\mathbf{x}) + \sum_{i=1}^P \nu_i h_i(\mathbf{x}) \right) \end{aligned}$$

- $g(\lambda, \nu)$ is a concave function, i.e. opposite of convex, single maximum also.
- We can find λ and ν by maximizing g :

$$\begin{aligned} \lambda^*, \nu^* &= \operatorname{argmin}_{\lambda, \nu} g(\lambda, \nu) \\ x^* &= \operatorname{argmin}_{\mathbf{x}} L(\mathbf{x}, \lambda^*, \nu^*) \end{aligned}$$

—> We have turned our constrained optimization problem into an unconstrained one.

Optimization in Short

- Convex functions have a global minimum.
- It can be found using either 1st or 2nd order methods. The latter is usually faster but requires computing second derivatives.
- Non-convex functions can be optimized in a similar manner but this will usually yield a local minimum.
- Constraints can be imposed using the Lagrangian formalism.
